University of Chicago, Chicago, Ill.—Two laboratory buildings on the University campus have low levels of surface radioactive contamination. These buildings are currently used by the University.

Harshaw Chemical Co., Cleveland, Ohio.—This very large building is located in a heavily industrialized area. Building surface and soil contamination were found to be above acceptable levels.

Simonds Saw and Steel, Lockport, N.Y.—This building was found to have localized sports where radioactivity was detectable. It is located in a heavy industrial area.

Horizons, Inc., Cleveland, Ohio.—Surface contamination exists in the building. It is located in an area mixed with light industry and residences.

Question. On page 9 of your prepared testimony before the Committee it is stated that "Extensive environmental monitoring is conducted at all of ERDA's major nuclear facilities. . ." What is the goal or purpose of ERDA's environmental monitoring system?

Answer. ERDA's nuclear facilities have conducted routine environmental surveillance programs for radioactivity since the earliest days of the atomic energy program. The primary purposes of these routine environmental surveillance programs were to determine whether (1) facility operations, waste treatment, and control systems were functioning as designed and planned from the standpoint of containment of radioactivity, and (2) the applicable environmental radiation and radioactivity standards and effluent control requirements were and are being met.

Question. Does such monitoring occur periodically or continuously?

Answer. The routine monitoring programs are part of a continuing program including the continuous collection of effluent data and periodic (daily, weekly, monthly, etc.) collection of environmental media samples (air, water, soil, vegetation, foodstuffs, and biota).

Question. In case of sudden, high levels of radioactivity, would you be alerted?

Answer. Yes. Routine effluent monitoring programs of airborne and liquid releases as well as inplant monitoring of facilities and operations do provide immediate indication of increases in levels of radiation. Procedures are established that prescribe reporting of levels of radioactivity.

Question. How is such information made available to the public?

Answer. On an annual basis, each contractor is required to prepare an Environmental Monitoring Report which summarizes:

(a) The results of effluent and environmental monitoring for radioactivity and radiation levels, and estimates of potential exposure to the public, and

(b) the degree of compliance with applicable Federal, State, and local regulations and standards for pollutants both radioactive and nonradioactive. The reports are submitted to the public and Federal, State, and local agencies. Additionally, these individual site reports are also published in an annual ERDA compilation.

More frequently, reporting of environmental and effluent data is performed by several contractors depending on public or local interest. For example, monthly meetings are held with public health and county personnel and the Rocky Flats personnel at which time data and information are exchanged and discussed.

Question. Do you maintain an up-to-date recordkeeping facility?

Answer. Yes. Recordkeeping is in the form of annual environmental reports, the raw data for which are retained at each facility. For effluents, ERDA maintains two computerized information systems which receive annually information on quantities of radioactivity released by each site. These systems maintain a historical record of release data.

Question. Please describe the effluents which you monitor.

Answer. Effluent monitoring for radioactivity includes all principal nuclides released in each airborne and liquid effluent and onsite discharge stream. For nonradioactive pollutants those specific substances identified in air quality regulations or in NPDES permits for liquids are monitored.

Question. How much money is spent on monitoring per year?

Answer. It is difficult to estimate the dollars spent on effluent and environmental monitoring but the most recent estimate, submitted to OMB in October 1976, is in excess of $20 million.

Question. You refer to studies that are being conducted in "a variety of places where significant levels of radionuclides have been released, such as Rocky Flats . . ." What are the results of these studies?

Answer. The environmental studies referred to deal with research into the mechanisms of movement of the transuranium elements in the environment and how they may change in various physiographic provinces where nuclear facilities are located. Our results to date indicate that greater than 99.9 percent of the plutonium released to the environment remains in soils and sediments. Of the small fraction found in biota, a major portion, about 90–99 percent is transferred from soil by physical processes of resuspension onto plant surfaces and animal pelts. An extremely small percentage is transferred to plants by root uptake in the food pathways to man and appears not to be a health hazard at the environmental levels found beyond ERDA facilities.

Question. In general, do you provide your data to EPA on more than a yearly basis?

Answer. These kinds of data are not routinely transmitted to EPA but are produced in topical reports and for scientific journals. The objective is to accumulate sufficient information so that predictive models for the environmental behavior of the transuranium elements can be made.

There is a routine monitoring program which measures the concentrations of radionuclides in the environs of certain ERDA facilities which coordinates with EPA:

At the Nevada Test Site there have been studies of the extent and nature of the radionuclide distributions. For those same locations, additional studies have concerned possible transport of the contamination to air, water, vegetation, small animals, and cattle. There is an interchange of this information with EPA through annual colloquia of the Nevada Applied Ecology Group.

At Rocky Flats Plant Site, where there is a small amount of distributed contamination, there have been studies of transport to vegetation, animals, and cattle; also, there has been a concentrated study there of an aquatic environment. Air and water have been monitored continuously for many years. All of the monitoring information is discussed each month with the Rocky Flats Monitoring Committee of which EPA is a member.

At Mound Laboratory there have been studies of plutonium-238 contamination that has been carried offsite in a drainage ditch. Air and water monitoring are done and reported to EPA annually.

At LASL there is a small amount of offsite contamination. Air monitoring is done; also, vegetation and animal life have been studied for possible uptake of contaminants. LASL monitoring data are published annually and are provided to EPA.

Question. Does your monitoring system interact with EPA's to a significant extent?

Answer. The ERDA environmental monitoring programs are site specific, i.e., they are designed with a facility and a specific set of problems in mind and they are geographically limited to locales around the site. In this respect, they do not interact with EPA systems which are generally designed to broadly sample across the United States. However, in special cases such as fallout sampling, the ERDA programs supply data to assure a complete coverage of potential fallout patterns. The environmental program at the Nevada Test Site is designed to cover the Western United States and in that respect duplicates part of the EPA network.

Question. Is ERDA promoting standardization of facilities as means of improving the safety of nuclear power plants?

Answer. An authorization request of $12.4 million B/A for FY 1978 ERDA funding of Light Water Reactor (LWR) Plant Standardization is included in the Senate Energy and Natural Resource Committee Bill and is pending authorization action by the House Science and Technology Committee. EDRA supports this request to develop and demonstrate plant standardization owing to the contribution standardization will make to the National Energy Plan (NEP) goals of reducing the licensing and construction delays of LWR's planned or to be committed in the future. The completion of plant standardization efforts already initiated is necessary in order to achieve "one-stop" licensing and to facilitate the prelicensing and utilization of banked sites for future power plant construction. This could reduce the licensing by as much as 2 years and reduce direct construction costs and schedules by $50 million and 1 year respectively. These objectives are not adequately being addressed by private sector initiatives because the industry's ability to make further investments necessary to complete customized plant designs for "one-stop" licensing review is currently seriously impaired. Therefore, the detailed and final designs needed for initial "one-stop" license application can only be achieved by standardized reference plants.

Although plant standardization will improve the safety of nuclear power plants through more reliable operation the principal motivation for this proposed program, consistent with the NEP, is to enhance the utilization of LWR's to offset a share of the Nation's energy deficit without undue risk of proliferation.

Question. On transportation of nuclear materials, what does ERDA do if its recommendations are not acted upon by NRC and DOT?

ERDA's actions in this event would depend upon the degree of detrimental impact, if any, on its operations. The final regulatory decision is up to NRC and DOT. ERDA could appeal if the action were adverse to ERDA's interests. Part of our effort in ongoing risk assessments and analyses, and confirmatory testing of modeling and analytical design techniques, is to assist NRC and DOT in their rulemaking efforts. Continuing close coordination between the staffs of ERDA, NRC, and DOT affords the opportunity to discuss ERDA's recommendations and determine the appropriate action to take.

Question. Has this ever happened?

Answer. No.

Question. What additional procedures, if any, are needed to ensure that nuclear materials are transported safely?

Answer. Protection of the public health and safety is a prime consideration for ERDA as well as DOT and NRC. The present packaging requirements which are published in the DOT and NRC regulations, and shippers' compliance therewith, has resulted in an outstanding safety record. In more than a quarter century of shipping radioactive materials there has not been a single incident which resulted in death or injury due to the radioactive nature of the material. Comprehensive risk assessment studies show that the risks to the public from nuclear shipments are comparable to the risks of being killed by a meteorite. Many environmental impact studies have gone through the formal review process; they all point out that the risks are very small. ERDA's testing and analysis programs have verified that the risks are already very low indeed. They are probably not worth trying to make even lower, based on the various cost-benefit studies which have been done. Nuclear shipments are made safely now, and we expect this experience to continue.

Question. What is ERDA's position on the Rasmussen report (AEC/Nuclear Regulatory Commission's Reactor Safety Study, An Assessment of Accident Risks in Commerial Nuclear Power Plants, WASH-1400)?

Answer. ERDA's position is that the study met its stated objectives of making an "estimate" of the public risks that could be involved in potential accidents in commercial nuclear power plants (LWR) and to compare these "estimates" with other natural and man caused nonnuclear accident events.

Its weakness is that the public and others are undecided how it should be used. This problem is being addressed this year by the Nuclear Regulatory Commission Risk Assessment Review Group. This Federal advisory committee was established to review the Rasmussen Report and make recommendations to NRC on both the risk methodology and how it could be factored into the regulatory process.

In addition, the results of the study must be used in the context of the stated objective. They cannot be taken out of the context of an "estimate," that is, an attempt to make absolute comparisons of nuclear and nonnuclear accident events assuming that the maturity of the data used is equal. Most of the nonnuclear data presented is based on a number of statistically significant actual accident events. On the other hand, there have never been any commercial nuclear power plant accidents resulting in nuclear-related fatalities, nor has there been enough actual reactor years of operation to provide the same degree of maturity to the nuclear data as to the nonnuclear data. Since the estimated probability of a significant nuclear power plant accident is very remote, it will take many decades of operation of hundreds of reactors to increase the maturity of the nuclear data to a point approaching that of the nonnuclear data.

In summary, studies of this type are useful in estimating the risks of any new technology in order to enable the public to better weigh potential risks against potential benefits in determining whether, and how, to pursue its development. They can also provide information on what subsystems and components affect safety to the greatest degree, and which, therefore, need emphasis during plant design and development program.

ERDA is using the results of an HTGR risk assessment study which uses similar methodology to WASH-1400 as a guide in identifying key areas of HTGR safety research which are needed. ERDA has used, and DOE will continue to use, every reasonable method at its disposal to insure that safety is recognized as an integrated part of the design criteria and development program for nuclear systems.

Question. In 19ı2 the BEIR report gave its stamp of approval to the linear hypothesis; since then, new doubts have been raised. Articles by Dr. Irwin Bross, Drs. Mancuso and Stewart and Dr. Ernest Sternglass seem to indicate that the problem of effects at low levels of exposure are more serious than the linear hypothesis would predict. Is there a need to reexamine the linear hypothesis?

Answer. The stamp of approval the BEIR report gave to the linear hypothesis was adopted as a conservative method of estimating health effects from low dose radiation exposure. For low LET (Linear Energy Transfer) radiation such as X-rays, gamma rays or beta particles found in fission products or fallout there is a large body of data derived from studies at the Inhalation Toxicology Research Institute (ITRI), the Oak Ridge National Laboratory (ORNL), the Argonne National Laboratory (ANL), and the Los Alamos Scientific Laboratory (LASL) indicating that effectiveness of radiation dose in producing biological damage decreases as the dose is spread out in time. This ability to repair radiation damage produced at low dose rates is being considered by the BEIR committee in their reevaluation of the linear hypothesis for low LET radiation. The hazard from low dose rate exposure is less than predicted using the linear model and standards may be revised to reflect this ability to recover from radiation damage. Studies at the Brookhaven National Laboratory (BNL), ORNL, ANL, the University of Utah, and the Pacific Northwest Laboratory (PNL) using high LET radiation such as neutrons and alpha particles show much less repair of biological damage. Laboratory studies (Utah, ANL, PNL) suggest that hazards of high LET radiation to do not decrease as the dose rates decrease. The shape of the dose response curve needs to be further defined at low total doses for this type of exposure.

The studies cited in Question 13 suggest a unique response to low dose low LET radiation exposure. The Mancuso-Stewart studies are described in more detail in Question 14.

Dr. Sternglass has published a large number of articles where he interprets his epidemiological data as supporting the concept that there is a uniquely damaging effect of radiation. These health effects are postulated to occur at doses in the range of the natural background (40–200 millirem per year). However, studies (ANL, NCI) show a negative correlation between natural radiation levels and cancer incidence, which suggest that radiation at this low level cannot be assigned a determinant role.

The molecular and cellular mechanism used by Dr. Sternglass to explain the low-dose-rate biological effects is that per unit dose the damage to the cell membrane increases as the radiation dose rate decreases. This was derived from an artificial cell membrane system which was degenerating and addition of free radicals catalyzed the auto-oxidation and breakage of the membrane. Very extensive experimental radiation research using molecular, cellular, and lifetime observation of several animal species show no evidence to support this hypothesis. A cause-effect relationship between cell membrane alterations at low doses and pathological changes in the intact animal has not been established.

Many statements and scientific reviews were made by members of the international scientific community in response to the claims by Dr. Sternglass on the hazards of low level radiation from fallout. These were compiled by the Atomic Industrial Forum and summarized by the U.S. Atomic Energy Commission, Division of Biology and Medicine. The hazards of low level radiation are under continuous review by the National Academy of Sciences, the National Council on Radiation Protection and Measurements, and the International Commission on Radiological Protection. The conclusions of all these groups represent the consensus of the scientific community and disprove Dr. Sternglass' claims—that fallout has produced significant health effects.

Dr. Bross' hypothesis is that certain human subpopulations are very sensitive to exposure to environmental insults. These subpopulations are postulated by Dr. Bross to develop cancer following low doses of radiation. If they are very sensitive to radiation, the shape of the dose response curve would be changed by this subpopulation so that a linear extrapolation from high dose data would underestimate the response at low doses. Experimentation is underway to identify and define the radiation response of subpopulations, i.e., animals with unique genetic background (BNL, ORNL) or aged (Utah, ITRI) and sick animals (ITRI), that will help determine if they are very sensitive to radiation-induced changes.

There is a continuing need to reexamine the shape of the dose response curves and the models used to predict the potential health hazards from ionizing radiation. Many research projects (ORNL, ANL, ITRI, PNL) are designed to determine the shape of the dose response curves under a variety of exposure conditions. Other research (ANL, UCD, LASL, BNL, ORNL) is directed to understanding the biological mechanisms at the cellular and molecular levels which produce the changes observed in the animal experiments. This combined research approach provides a valuable data base used by committees like BEIR, NCRP, and ICRP in risk evaluation. Such committees use these data to develop standards made to ensure that the health and welfare of the public will be protected.

Question. Have funds been spent in fiscal year 1977 for this purpose? Are funds budgeted in fiscal year 1978?

Answer. In this broad context, funds for investigation and evaluation of the linear dose-response hypothesis were allocated in fiscal year 1977 and are budgeted for fiscal year 1978.

Question. Dr. Mancuso's study of Hanford atomic workers was being funded by ERDA, but after an unfavorable peer review, his funding was terminated. Was his research reviewed by radiologists or epidemiologists?

Answer. The contract with the University of Pittsburgh, "Study of the Lifetime Health and Mortality Experience of ERDA Contractors," principal investigator Dr. T. F. Mancuso, was routinely reviewed over the years. The expertise of the members of the review teams primarily reflected the areas of biostatistics and epidemiology.

Question. Why was his support discontinued?

Answer. The decision to terminate the contract with the University of Pittsburgh and to transfer the study to Oak Ridge Associated Universities (ORAU) was made because of deficiencies in performance under the contract. These included a reluctance to initiate analyses of available data, to publish papers in edited journals, and to have the contents of their reports quoted or cited. Also, serious questions were raised at the scientific reviews about the quality of the statistical analyses. Major disagreement between the investigators in the study and ERDA scientific staff arose from the investigators' desire to enlarge the population under study to include all major AEC/ERDA facilities. ERDA staff was of the opinion that enlarging the study would not solve the intrinsic deficiencies of the study and that the biases that tend to make control populations imperfect are independent of the population size in a study of this type. Accordingly, the study was transferred to ORAU so that completion of data base and analyses can proceed on a more timely basis.

With regard to the reference to studies by Drs. Mancuso and Stewart in Question No. 13, results of the analysis of the cause of death of Hanford workers by Drs. Mancuso, Stewart, and Kneale have now been published in a final report to ERDA. A review of this report by an *ad hoc* committee, consisting of experts in radiation epidemiology and other independent experts, indicates that the claimed increased incidence of cancer in Hanford workers appears to be the result of inappropriate use of statistical methodology. Hence, the results of the Mortality Study of the Hanford workers cannot be used to evalute the validity of the linear hypothesis.

Question. EPA has revised the uranium fuel cycle exposure standard to 20 mrems/year. Does ERDA comply with this standard?

Answer. The EPA regulations by definition apply to "radiation doses received . . . as the result of operations which are part of a nuclear fuel cycle." Thus, the regulations do not apply to ERDA facilities except those parts of the gaseous diffusion plants providing enrichment services to the electric utilities, and these do comply with the EPA standard.

Question. If the new evidence on the nonlinear hypothesis is considered valid, would ERDA or NRC revise this standard further?

Answer. As this is an EPA regulation, it would be incumbent on them to revise the standard rather than NRC or ERDA. Should such information be developed through ongoing ERDA research, our assistance in revising standards, as necessary, could be counted on.

Question. In your prepared testimony, you refer to "the latency effects in humans . . .". What is the range of latency periods for various radiation effects in humans and do we have an understanding of the variation in these latency figures?

Answer. The mean latency for radiation-induced tumors in humans depends on a number of factors related to the type and magnitude of radiation exposure, the characteristics of the population exposed, the characteristic of the type of tumors induced and the circumstances of surveillance of the exposed populations. From published estimates, the mean latency of radiation-induced malignancies for different types of tumors ranges from 20 to 30 years. Moreover, by nature of the methods used to determine mean latency, the values quoted are unlikely to over-estimate the value and the true value for some malignancies must be much larger. In addition, new cases of radiation induced tumors may continue to appear at a much longer period following exposure.

Example of the complex interrelation between population characteristics and radiation exposure is demonstrated by findings on the incidence of leukemia, breast cancer and lung cancer in the Japanese populations in Hiroshima and Nagasaki.

Type of leukemia	Time of maximum risk of leukemia following exposure—age at time of exposure (years)			
	Less than 15	15 to 29	30 to 44	More than 45
Acute form	6–7	10	15–16	>20
Chronic form	6–7	7–8	9–11	-------------

It is evident that the younger at the time of exposure the greater risk at an earlier period while in the group aged 45 or more the greatest risk occurs later. With regard to the latter group, there is no evidence at present that the risk for leukemia has returned to the levels in the controls.

An increased incidence of breast cancer in women who were exposed was noted before 1955 in older women and is now being maintained and augmented by women who were younger when exposed. Based on information available now, it appears for those women who were below 10 years of age at time of exposure, the peak effect lies well in the future, i.e., a latency period of more than 30 years.

An analysis of the data in 1957–1958 suggested that the incidence of lung cancer was significantly elevated in exposed populations. Since then, three dose specific analyses have strengthened the evidence. Even more than is the case of breast cancer, the increased incidence now visible is in the older age groups at time of exposure. There is every reason to expect that the peak effect for those below the age of 35 years at time of exposure lies in the future.

Question. Are the epidemiological studies conducted at Los Alamos and Argonne contributing to this effort?

Answer. The epidemiological study of the radium dial painters at ANL indeed has contributed significantly to various factors that determine the latency of tumors induced by radium. The LASL epidemiological study of plutonium workers, initiated in 1974, will, in the near future, develop information on tumor latency in this population.

Question. What is their present status and what preliminary findings have been reported, if any?

Answer. *Status of Studies on Radium-Exposed Human Populations* (Argonne Radium Studies). Much of the research effort on radium effects has been aimed at clarifying dose-response relationships between radium exposure and bone cancer. The rationale for such work is its relevance to assessment of risks related to other almph-emitting radionuclides, to which human populations may be exposed (e.g., plutonium, thorium, uranium).

In addition to studies on bone cancer (including incidence rates, "latency" periods, dose-response functions), however, other possible health effects are being assessed through studies on mortality from various causes (site-specific cancers and other chronic diseases).

More detailed descriptions of the results of these studies are provided below.

BONE CANCER

A theory of the induction of bone cancer by alpha radiation is being developed, and an extensive preliminary report has been published (Marshall and Groer, 1977). Using data on humans exposed to radium, the evidence at present supports a dose-square model better than a linear (or linear + square) model; more definitive conclusions await a more thorough cohort analysis and more complete follow-up on human populations. The theory (Marshall and Groer, 1977) provides some predictions on the bone tumor rate over time and the relative effects of alpha-emitting nuclides with different half-lives, and describes the possible mechanisms and stages of carinogenesis involved.

An analysis of "latency" periods or appearance times of bone cancer in radium-exposed humans (a subgroup composed of early female dial painters) has recently been completed (Polednak, in press). The time period from first exposure to diagnosis of bone cancer ranged from about 5 to 52 years, with a log-normal distribution. Although mean and median latency periods declined with increasing intake levels of radium (measured in microcuries), this apparent effect of intake dose was due to "competing risks" (i.e., a dose-related increase in mortality from causes of death other than bone cancer). Correcting for this effect by life-table methods, incidence rates from bone cancer were consistently higher in a higher intake-dose group (than in a lower intake-dose group) at each time period after exposure. There was no significant effect on intake-dose, at tumor-producing levels, on the pattern of incidence rate over time after first exposure to radium.

Other current analyses have involved dose-response relationships for bone cancer in the best-defined and most-completely followed-up radium cases—i.e., the early female dial painters (first employed before 1930). Again, present data provide more support, in a statistical sense, to a dose-squared relationship (Rowland, Stehney and Lucas). Current efforts are concentrated on measurement of radium body-burdens in this group, either by exhumation (for the deceased) or increased efforts for cooperation in the study (for those still alive). Sample sizes are of critical importance in evaluating dose-response relationships. The implications of this research concern risk assessment of human exposure to alpha-emitting radionuclides, recognizing that there will be differences among these radionuclides in terms of probable route of exposure, metabolism, organs at risk, and expected effects.

MORTALITY STUDIES

A recent report (Polednak, Stehney and Rowland, in press) presents data on mortality from various causes in a group of women first employed before 1930 in the dial-painting industry, and who were ascertained from sources largely unrelated to outcome (i.e., mortality). This is the most "unbiased" group of radium-exposed humans, since inclusion in the study was not dependent on presence of symptoms or disease, or level of exposure. Some 640 (or 88.3%) of these 725 women have been followed up in terms of mortality.

Based on health rates for U.S. white females, greater than expected numbers of death (from death certificates) were observed for all causes (240 observed vs. 196.7 expected), "bone cancer" (22 vs. 0.3), cancer of other and unspecified sites (18 vs. 2.6), diseases of blood and blood-forming organs (4 vs. 1.1) and "external" causes (31 vs. 10.2). Six of 22 certificates coded to "radiation accident" (an "external" cause) also mentioned bone cancer. From sources other than death certificates, many of the "other and unspecified" cancers were shown to be cancers of bone and/or sinuses (mastoid or paranasal). No other causes of death showed statistically significant increases over expectation.

Dose-effect relationships were assessed indirectly and directly. Compared with women first employed in 1915–24, those first employed in 1925–29 had low cause-specific mortality ratios (observed vs. expected numbers of deaths) and an overall mortality ratio of 0.80 (or 80% of expected). This pattern corresponds remarkably to well-documented changes in work habits in the industry; i.e., in 1925–26, oral contact with paint brushes was prohibited, leading to reduced intake of radium.

In comparisons by time period (<1945, 1945–64, and 1965–75), a significant excess of deaths from leukemia and diseases of blood were observed before 1945 only.

Due to problems of bias in follow-up, only the late effects of radium exposure could be assessed directly in terms of dose (intake level). Among women alive in 1954 (when extensive studies were initiated) and measured for radium body-burden at least once while living (in 1954 or later), observed mortality was compared with that expected on the basis of U.S. white female death rates. Follow-up was from the year of first measurement of radium body-burden. Total mortality (from all causes of death) was analyzed in 5 intake-dose groups. For 3 groups below 50 μCi, total deaths were less than expected (i.e., about 80 percent of expected), while for two higher dose groups (>50μCi), total deaths were greater than expected (i.e., about 200 percent of expected). Cause-specific mortality was analyzed in two dose groups (<50 and $\geq$50 μCi). In the lower dose group, the only cause category with a significantly greater number of observed than expected deaths was cancer of the colon; the mortality ratio for all causes was 0.82 (or 82 percent of the expected number of deaths). In the higher dose group, the mortality ratio for all causes was 1.88 (or almost twice the expected number of deaths). The possibility of a causal association between lower-dose radium exposure and cancer of the colon needs to be explored further, by continued follow-up of the present group of measured women, and clinical studies (to verify diagnoses and describe the pathology). The present findings are not proof of causality, since a large number of comparisons were made, and some may reach the conventional level of statistical significance merely by chance alone.

No bone cancers or leukemias were observed in measured persons with an intake of <50 μCi of radium.

In this study of late effects of low level of radium, a cut-off point of 50 μCi was used. For a woman who worked for one year (about the average for this group) and had an intake of 50 μCi, the maximum body burden of radium-226 was about 2.5 μCi. This is about 25 times the radiation protection guide of 0.1 μCi of radium-226, regarded as being the maximum permissible body burden from occupational exposure, and as being relevant to other bone-seeking radionuclides such as plutonium-239 in humans.

Further work should concentrate on the following areas: (1) use of morbidity data, in view of the limitations of death certificates; (2) obtaining body-burden measurements on these early dial workers who are now unmeasured. The second point is relevant to the accuracy of the above conclusions regarding dose-response relationships, as well as those specifically dealing with bone cancer and models of induction described above. In the above-mentioned mortality study (Polednak et al.. in press), about 70 percent of those women still alive in 1954 had had a body-burden measurement. Although such response rates are not unusual in epidemiologic studies, questions exist about the generalization of findings on the measured group to the total group.

Question. According to your testimony, studies of the health effects of radiation are being conducted by several groups. You caution, however, that these are lifetime studies of latent effects of radiation and, therefore, short-term information is preliminary. However, some of this information dates back a generation, such as the plutonium workers of 1942, the thorium workers from 1935 to 1974, and the radium dial painters.

How is this data being used by your Division of Operational and Environmental Safety to ensure the safety of workers currently exposed?

Answer. The radiation workers exposure standards which are adopted by ERDA are based upon the recommendation of the National Council on Radiation Protection and Measurements and the International Commission on Radiological Protection. These organizations have access to the results of the epidemiological studies and use them as a basis for standards development. In addition, the Division of Operational-Environmental Safety monitors the current studies to see whether there is evidence which questions the adequacy of our standards.

Question. In the study conducted from 1944 to 1945, 26 workers at Los Alamos were examined for effects of plutonium deposition. You state that "no evidence of disease associated with plutonium deposition was observed". What were the levels of exposure?

Answer. Of the 26 workers, 2 workers have more than 5 maximum permissible body burdens (MPBB), 18 have between 1 and 5 MPBB and 7 have less than 1 MPBB.

Question. You say that research emphasis is given to exposures to low levels of external radiation that might occur in work areas or in the general environment. Can you describe this research in more detail?

Answer. ERDA supports animal research using both dogs and rodents to determine the hazards associated with low levels of external radiation. These projects are designed to aid in evaluation of the long-term health consequences of both high LET (neutrons) and low LET (gamma rays) radiation. Since cancer induction is a principal hazard of low level radiation exposure and since the time between exposure and cancer appearance may be very long, it is essential to obtain data from long-lived dogs as well as rodents.

At Argonne National Laboratory (ANL), special facilities are available for continuous exposure of dogs to low dose rates (35–0.4 rads/day) gamma irradiation. Dogs were exposed at dose rates of 35, 17, 10, and 5 rads/day to reach total doses of 600–4000 rads. Lifetime observations have been completed on these dogs. At 5-10 rads/day, 50 percent of the dogs developed myelogenous leukemia. Doses of 10 r/day interfere with normal development of the testes and 5 r/day causes changes in developing ovaries. These exposures are, of course, much higher than the maximum permissible occupational dose of 5 rems per year. Additional experiments have been initiated in which dogs will be exposed to lower dose levels (5, 2.5, 1, and 0.4 rads/day) throughout their lifetime. This research will make it possible to evaluate the effects of lifetime exposure to lower doses and dose rates.

Studies at the University of California, Davis (UCD) complement those at ANL by evaluating the cellular changes induced in bone marrow under exposure conditions that lead to the induction of leukemia. These studies which utilize dose rates of 15, 5, 1.5, and 0.5 rads/day are designed to gain information about the mechanism of transforming normal cells to leukemia and also to attempt to develop sensitive cellular indicator systems of low-level radiation damage.

Groups of pregnant female dogs (ANL) are exposed to evaluate the effects of *in utero* radiation. The offspring are studied to determine tumor induction and developmental patterns. The sensitivity of *in utero* radiation exposure can thus be evaluated and used to estimate hazards. The study will also determine if reproductive integrity is maintained following *in utero* and lifetime low dose rate exposures. This is important in light of the observations made at Lawrence Livermore Laboratory (LLL) that the developing ovary is very sensitive to radiation damage.

Rodent studies are useful in establishing the relative risk of exposure to low dose and dose rate radiation of different types. At ANL and Oak Ridge National Laboratory (ORNL), rodent studies have been completed to determine the shape of the dose-response curves for neutrons and gamma rays using either chronic or fractionated radiation schedules. The results in terms of life shortening and cancer induction following neutron exposure have been compared with data derived from animals receiving gamma ray exposure. Thus, it is possible to determine the relative hazards of the two exposure types at high and intermediate doses. For neutron exposures at intermediate doses, protraction of the dose over a longer time period or fractionation of the exposure into several small doses increases the amount of life shortening and cancer incidence per unit of dose above that measured following a single exposure. In most experimental systems, the neutron exposures seem to be more damaging than gamma exposures. Studies are in progress which extend these observations to much lower dose rates and total doses. These rodent studies utilize dose rates of 0.2, 0.8, 3.2, and 12.8 rads/day to produce total doses of 2.5, 5, 10, 20, and 40 rads. With these 20 group of mice, it will be possible to determine the effects of both low dose and dose rates on the shape of the dose response curves for the induction of radiation-induced disease by neutrons. The hypothesis that low dose rates produce a higher frequency of cancer than predicted by high dose rate studies can, thus, be tested. This information will be useful not only for evaluating the hazards from neutron exposure but will form a part of the data base for risk evaluation for alpha emitters and other high LET radiation.

Animal studies (ORNL) on the genetic hazards from low levels of external radiation form the data base for evaluation of this hazard in man.

In female mice, high dose rates produce significant mutation rates while low dose rates exposures do not increase the mutation rate above that observed in controls. Studies at low dose rates indicate that somatic cell chromosome aberrations (ITRI, ORNL) and gene mutations in male mice (ORNL) decrease as the dose rate is lowered to levels of about 1.0 r/min. Further reduction to very low dose rates .005 to .0007 r/minute gives no further reduction in mutation or chromosome aberration frequency. Other studies are in progress to evaluate the physiological and genetic significance of mutations and aberrations since all these may not produce adverse effects in offspring.

The data thus suggest a decrease in genetic hazard with a decrease in dose rate for low LET radiation.

The following research projects are concerned with the biomedical effects of radiation on human populations.

1. A study of the health and mortality of workers in the nuclear industry in Hanford and Oak Ridge since 1942 (approximately 130,000).
2. A study of the health and mortality of all U.S. plutonium workers since initiation of the Manhattan Project (approximately 15,000).
3. A study of the health and mortality of A-bomb survivors in Japan (approximately 109,000).
4. Medical surveillance of Marshallese exposed to fallout from nuclear weapons tests (approximately 150).
5. A study of the mortality of persons with internal deposition of radium (3100) and thorium (4500).

With the exception of a relatively small group of A-bomb survivors in Japan, these populations have been exposed to low levels of external or internal radiation.

Question. Does the Transuranium Registery form a large part of your data base?

Answer. The U.S. Transuranium Registery (USTR) is developing a data base of workers with known depositions of transuranic elements. As such, the information collected on long-term biological effects as a function of actual tissue deposition is a vital part of the epidemiological study of plutonium workers.

Question. How can this be considered a reliable source of information if participation by various facilities is strictly voluntary?

Answer. There exists excellent cooperation on a voluntary basis of the laboratories and contractors with the USTR in this effort which makes this a highly reliable source for valuable information.

Question. You have testified that ERDA is giving special research attention to the dangers of inhalation exposure of radioactive materials because of its significant exposure potential. How often do accidental releases of radioactive materials into the atmosphere occur?

Answer. In the last several years, accidental releases of radioactive materials have occurred rarely. The following is a listing of reportable incidents which resulted in an atmospheric release.

Year	Radionuclide	Location
1970	Tritium	Lawrence Livermore Laboratory.
1974	Tritium	Savannah River Laboratory.
1975	UF_6	Portsmouth.
1975	UF_6	Portsmouth.
1975	Tritium	Savannah River Plant.
1976	85_{kr}	Oak Ridge National Laboratory.

In the last 6 years these six incidents were those reportable under criteria established by ERDA for reporting and formal investigation of accidental releases.

Question. What materials are released and in what phase of the nuclear energy cycle?

As indicated above, the nuclides released were tritium, ^{85}Kr, and UF_6. The UF^6 is used in the enrichment process and as such is the only release related to the nuclear fuel cycle. The remaining releases were from research facilities or from facilities involved in ERDA's weapons development programs.

Question. Is the inhalation exposure resulting from these releases the only source of serious exposure hazard?

Answer. These releases have not resulted in a serious exposure hazard to either the occupational or offsite population at ERDA facilities. There are other pathways through which potential exposures could occur, for example, liquid effluents. However, no serious exposure hazard has been shown to be a consequence of these pathways.

Question. How serious a threat to human health are these releases, both to workers at the nuclear site and the general population?

Answer. As reported in the annual Environmental Reports and presented at technical meetings, effluents from ERDA facilities are less than 1 percent of established standards. In fact, for all ERDA facilities, the relative percent of facility population dose to background (natural) population dose is about .02 percent and has remained at this level for the last 4 years. These values include those accidental releases that have taken place.

In the six incidents which were reported in the last 7 years, four workers received measureable radiation doses, all of which were less than 5 percent of the maximum allowable limit.

Question. You mentioned the implementation of a new program wherein the weather patterns around the site are analyzed, allowing the prediction of the direction in which a radioactive cloud would move and facilitating an evacuation should the situation warrant such action. Why has ERDA failed to consider this measure an essential part of its safety program before now?

Answer. All ERDA nuclear sites have an atmospheric release prediction system as an integral component of their emergency response measure. Each site has meteorological equipment, manpower and predictive tools tailored specifically to the site to respond to potential or actual incidents or accidents involving an atmospheric release of hazardous material.

The Atmospheric Release Advisory Capability (ARAC) development was conceived by the Division of Biomedical and Environmental Research in 1972 in response to the anticipation at that time that several hundred nuclear power reactors would be operating in the United States at the end of the 20th century. It was thought that the development of a centralized advisory service, utilizing state-of-the-art regional predictive models, computers, communications, and display systems would greatly reduce the need to duplicate these services at each site while at the same time improving predictive methods generally in use at the time.

The development of the system is nearly complete and the concept appears to be valid. Before offering the concept to the nuclear power industry, however, the plan is to equip a large number of ERDA nuclear sites with the ARAC system to prove its utility and demonstrate its validity. The implementation phase of this very expensive system is scheduled to add about two or more ERDA sites per year until all requiring the service are equipped.

Question. When will NRC begin implementing this technique and will it be required of licensees?

Answer. The Nuclear Regulatory Commission has been following the development of ARAC since its inception, but we are unable to answer for them what their plans might be.

Question. You mention techniques for treating individuals exposed to internally deposited agents, presumably including inhalation. What kind of techniques are these? How effective are these?

Answer. At present, the only drug available for treating individuals exposed to internal contamination with actinides is the tri-sodium calcium salt of diethylenetriaminepentaacetic acid (DTPA). DPTA binds actinides and accelerates urinary excretion thus preventing deposition in tissue. The agent is quite effective in reducing the body deposits of soluble actinides. In a recent case of unusually severe internal contamination with a soluble actinide, well over 85 percent was excreted within a 30-day period following contamination. In comparison, the biological half life of this particular actinide in the absence of treatment, is about 73,000 days. However, for the deposition of highly insoluble oxides or depositions that have become firmly bound to tissues, neither DPTA nor any other agent have been proven useful in decreasing internal deposition in animal studies and in man.

Question. How seriously do you view the possible health effects associated with increasing ionizing radiation exposure of the general public due to increasing use of diagnostic medical and dental X-ray procedures?

Answer. Conventional risk assessment is based on linear extrapolation, i.e., the relationship between effects and dose remains the same irrespective of changes in dose, dose rate or population at risk. Linear extrapolation is the only means to assign risk to exposure from most diagnostic exposures since at these dose levels epidemiological studies are not feasible. By using the linear extrapolation, it is implied that any dose contribution is associated with increased risk. On this basis, exposures should be kept as low as possible.

Question. How does the average population exposure from the nuclear fuel cycle compare with the average population exposure from such diagnostic procedures? How is it likely to change in the future?

Answer. The current estimated population exposures from diagnostic procedures is about 50 mr per year. Estimated annual dose contribution from current reactor operations and nuclear fuel cycle are approximately 0.04 mr per year. For the projected nuclear installed capacity of 3600 GW by the year 2000, the whole-body collective dose would be less than 3 mr per year. In comparison, the annual dose (whoe body) from natural radiation in the U.S. is about 100 mr per year.

Question. In his testimony Dr. Liverman indicated that coal-fired generators burning western coal would release significant amounts of radioactivity into the atmosphere. A recent New York Times article noted that some scientists had predicted that several thousand deaths would result simply from the normal, non-radioactive emissions that pollute the air. How much money has ERDA allocated to investigate the effects of increasing airborne pollutants, both radioactive and non-radioactive from an increase in the number of coal burning power plants?

Answer. The health effects program in ERDA does not specifically address health problems associated with radioactive pollutants from coal burning facilities. A recent report "Potential Radioactive Pollutants Resulting from Expanded Energy Programs" (EPA CHESS Report No. 6), from Stanford Research Institute estimates that with accelerated coal combustion in the ERDA National Plan for Energy RD&D the total radiation does to man will increase in the year 2000 to about 1,500 man rems per year which is less than 0.01 of 1 percent of the natural background radiation level. The airborne radioactive pollutants from coal combustion facilities with stack cleanup will be from the fly-ash particulates found in waste ash piles and ponds. Most will be from radioactive gases such as radon emanating from transuranic elements in the trapped fly ash. Some studies using experimental animals under controlled laboratory conditions indicate that inhalation exposure to radon gas in the absence of dusts is not a significant health hazard. The estimates given in the aforementioned report are for a "worst case."

The health effects program does not specifically address those problems related to radioactivity involved in coal combustion because the same pollutants are also encountered in parts of the nuclear energy fuel cycle. Such evaluations are therefore provided as part of the fiscal year 1978 allocation of $35.5 million for nuclear energy-related research. That program includes the necessary research to provide health risk estimates from low-level exposure to external radiation and those radionuclides to which man might be exposed at all stages of the nuclear fuel cycle from mining to disposal of radioactive waste. At the same time, that program addresses potential health problems identified with radioactivity encounterable in other energy technologies including coal combustion.

The fiscal year 1978 budget includes about $15 million for assessment of health risk from all coal technologies and allocates $3.9 million specifically for evaluation of the health effects of non-radioactive atmospheric and other effluents of conventional coal-burning facilities as well as advanced coal combustion processes (fluidized-bed combustion) under development in the ERDA fossil energy program.

The aim of these programs is to produce the types of comparative health risk data required for choice among the several alternatives available for increasing electric power production namely; nuclear, conventional, and advanced coal combustion.

Question. What alternatives are available in case the radiation dangers from coal are too great?

Answer. As indicated in the response to the above question, the radiation hazard from coal combustion by the year 2000 is estimated to be about 1500 man rem or 0.01 of 1 percent of that resulting from natural background radiation. This can be compared with estimates of about 130,000 man rem total dose from accelerated nuclear power development including breeder reactors and required fuel reprocessing facilities. Most of this total dose is from fuel reprocessing and represents less than 1.0 percent of that received from natural background radiation. Although the radiation hazard associated with coal combustion may be significant, it is not likely to be the major contributor to decisionmaking among the various alternatives for future energy production. In our present state of knowledge, it is easier to estimate the hazard from radiation than for most chemical pollutants. The ERDA health effects program is geared to providing the information that is needed to compare the health risk associated with the various options available for energy production and conservation. It also can provide the data required to improve methods for control of nuclear and chemical pollutants.

Question. What research is ERDA conducting on the health effects of high-voltage transmission lines?

Answer. ERDA is currently sponsoring a multidisciplinary program of research to identify and characterize health effects that may be induced by electric and/or magnetic fields associated with high-voltage (HV) overhead transmission lines (both DC and 60 Hertz AC types). This is a coordinated program jointly funded and managed by ERDA's Division of Electrical Energy Systems (EES), Division of Biomedical and Environmental Research (BER), and Division of Environmental Control Technology (ECT).

Research dealing with electric fields includes both biological studies *per se* and work conducted to characterize physical-chemical perturbations to which biological systems may be exposed in the vicinity of HV transmission lines. In the biological investigations, electric-field intensities under study vary over several orders of magnitude and span the entire ambient range. Summarized below are studies that are ongoing or just getting under way:

A study of animal responses to 60 Hertz electric fields (field strengths up to about 130 kV/m) is in progress at the Pacific Northwest Laboratories (PNL). Both rats and mice are being tested to determine possible effects of long-term exposures on a number of biological parameters including growth, development, reproduction, metabolic activity, endocrine function, immunologic competence, bone growth and structure, serum chemistry and hematology, nerve and neuromuscular function, behavior, and pathology. Only very preliminary data have been collected to date. A companion study in miniature swine is sponsored by the Electric Power Research Institute (EPRI).

In a second study at PNL, possible mutagenic effects of DC and 60-Hertz AC fields are under investigation in two genetically well-characterized systems, Drosophila (the fruit fly) and microorganisms. Bacterial cells are being exposed in an aqueous conducting medium while Drosophila (pupal stage) are exposed in air. This is jointly managed by EPA and ERDA/BER and is supported by EPA pass-through funds. Data collection is just beginning.

Psychocoustic responses of humans to audible noise associated with HV transmission lines have been under investigation at the National Bureau of Standards (Sound Division) for nearly two years. The noise of concern may be generated by corona phenomena during wet or humid weather. Although this noise is of relatively low intensity, it may constitute an annoyance in nearly areas. Behavioral measurement techniques are being used to evaluate aversiveness to the audible noise. A pilot study involving a small number of subjects has been completed, and data from the first full-scale experiment are being analyzed.

At the University of Rochester, a multifaceted study of biological responses to HV transmission lines is getting under way. Responses to 60-Hertz electric fields of various intensities and to transient electric shocks are to be characterized. Thresholds for perception of and aversion to electric fields will be studied in the rat. Responses to transient electric shock (spark discharge) will be similarly investigated. Physiological studies with rats and mice will be conducted to identify any somatic effects that may be induced by chronic exposure to electric fields. Additional studies with simpler systems grown *in vitro* or in tissue culture are planned to define effects of electrical fields on cell division, growth, differentiation, chromosome morphology, and viability. One purpose of the Rochester study is to test biophysical models which predict that the response of living systems to electric fields is a threshold phenomenon.

Another recently initiated project involves a joint effort by investigators at the Sandia Laboratories in Albuquerque and the Los Alamos Scientific Laboratory (LASL). In the LASL effort, mammalian cells are exposed *in vitro* (conducting medium) to 60-Hertz electric fields to evaluate possible genetic changes or perturbations of cell replication, growth, or survival. Effects on chromosome structure will also be investigated. These experimental activities will be closely integrated with a theoretical study at Sandia of rate processes in both exposed and unperturbed systems. A study of bioeffects of 60-Hertz magnetic fields will be added during the next year.

The ERDA staff (in EES) has been participating in the management of a project at the University of California (Los Angeles) which has been jointly funded in the past by EPA/DHEW/ONR and in which possible effects of 60-Hertz electromagnetic fields on the central nervous system (CNS) are being evaluated. The study is planned so that effects on CNS function and behavior can be identified and correlated with measured changes in brain rhythms and neuronal membrane conditions. ERDA was recently added to the list of fiscal sponsors for the UCLA project.

The Sanford Research Institute is currently reviewing and analyzing recent literature dealing with health/environmental impacts of HV overhead transmission lines in order to assess the adequacy of environmental control technologies.

A study of electric field instrumentation and calibration is being conducted by the staff of the Electricity Division, National Bureau of Standards (NBS). The objectives of this project are to evaluate devices and methods in current use for measuring electric and magnetic fields associated with HV, AC and DC transmission lines, to assess methods being used for calibrating such devices, to develop and document a recommended standard procedure for performing calibrations, and to establish a calibration facility at NBS. Work on AC field meters is nearing completion.

A study recently initiated by the General Electric Company will establish a data base on the characteristics of electric fields and air ion concentrations that are associated with DC transmission lines operating from ±600 kV to ±1200 kV. The data base will be assembled from measurements made near and under a DC line. Data will be collected under diverse weather conditions and for a variety of conductor configurations and line voltage levels.

The Federal Register of March 18, 1975, carried a notice from EPA requesting information and data on health/environmental effects of transmission lines energized to 700 kV or higher. Over 50 responses from a variety of sources were received. A preliminary review of these responses as well as information from other sources failed to identify any acute impacts. A detailed analysis of the information submitted in the 50 responses is needed, however, and work on this task is now getting underway at the Illinois Institute of Technology Research Institute under joint funding by EPA and ERDA. The analysis should be completed in one year.

All ongoing studies of magnetic fields were initiated in Fiscal Year 1977 and, accordingly, are not far advanced. Although these are, at present, generic studies (not necessarily limited to any one type of magnetic field) primarily concerned with relatively high field strengths, they will nonetheless provide valuable baseline data relevant to bioeffects that may be induced by the weak fields associated with HV transmission lines. The following work is in progress:

At the Lawrence Berkeley Laboratory (LBL), a variety of experimental systems is being used to identify and characterize biomagnetic phenomena, particularly generic phenomena. A principal objective of the LBL project is to develop an understanding of such phenomena in terms of mechanisms and theory. Special emphasis centers on the study of cellular systems and tissues (e.g., nerve and retinal tissue) that may be particularly sensitive to electromagnetic and paramagnetic effects. A facility for exposing small animals is being developed. Preliminary data have been obtained in a study of effects of strong (1–4 kilogauss) static fields on growth and development in two different test systems (an insect and a mold).

Also in progress at LBL is an epidemiological study of some 2000 scientists and technicians who have been exposed to over 4000 "gauss days" per year for at least five years.

A range-finding study of biomagnetic responses in animal and cellular systems was recently initiated at the Pacific Northwest Laboratories. Work is getting underway on the study of magnetic field effects on growth, development, behavior, and other endpoints in mice and trout. Possible mutagenic effects, clastogenic action (alteration of chromosome patterns), modification of nerve function, altered cell growth, and other responses will be investigated in simpler test systems.

Genetic effects of static magnetic fields in two well-standardized test systems, Drosophilia and Tradescantia (a flowering plant), are being investigated in a study at the Brookhaven National Laboratory.

Question. Are you aware of the work of Marino and Becker at the VA Hospital in Syracuse, New York?

Answer. Yes. Both ERDA staff and contractors are familiar with the relevant scientific publications of Drs. Marino and Becker as well as their testimony before the New York State Public Service Commission during the recent licensing hearings on two 765 kV transmission lines (Cases 26529 and 26559). One of the purposes of ongoing studies at the University of Rochester and the Pacific Northwest Laboratories is to evaluate specific experiments that Dr. Marino has previously conducted and reported.

Question. How much money does ERDA plan to spend on non-ionizing radiation research next year?

Answer. It is planned to initiate at least two studies of electric-field bioeffects in fiscal year 1978. Some expansion of research on biomagnetic effects is also anticipated. In addition, several studies sponsored by the Bonneville Power Administration (Department of Interior) will be added to the above-described program as both ERDA and BPA become a part of the Department of Energy. The ongoing BPA research includes field studies to evaluate impacts of HV AC and DC lines on nearby biota and ecosystems as well as efforts to quantify electric fields, ion densities, and ion currents associated with DC lines. Summarized below are current ERDA projections for fiscal year 1978 (with fiscal year 1977 figures included for comparison):

[In thousands of dollars; fiscal years]

	Funding	
	1977	1978
Electric field studies:		
ERDA/EES	1,000	2,640
ERDA/BER	[1]210	[1]626
ERDA/ECT	33	49
Subtotal	1,243	3,315
Magnetic field studies: ERDA/BER	550	900
Total support	1,793	4,215

[1] Includes 70 in EPA pass-through funds.

Question. Is ERDA's research being coordinated with EPA?

Answer. Yes. As mentioned above, ERDA and EPA are cooperating in the funding and/or management of three research projects. In addition, the ERDA staff interacts in other ways with the technical staff of EPA's Office of Radiation Programs. A representative of that Office is a member of the Interagency Advisory Committee on Electric Field Effects from High Voltage Lines, which is chaired by Mr. Robert W. Flugum of ERDA/EES. Additional interactions occur at meetings sponsored by the Office of Telecommunications Policy, at scientific meetings, and by telephone or visits.

Question. During the hearing, you indicated a decision to transmit solar energy from space to earth via microwaves would require a considerable increase in research to study the effects of microwave radiation. Does ERDA have plans to conduct a study on this subject?

Answer. Yes. Representatives of NASA and ERDA have been working together for about eighteen months to develop a joint program for assessing the feasibility of NASA's concept of solar energy utilization based on a satellite power system (SPS), whereby solar energy collected in space would be transmitted to earth via a large microwave beam for subsequent conversion to electricity. As a result of this interaction, a detailed, two-volume "SPS Concept Development and Evaluation Program Plan" was completed in May 1977 and subsequently formally approved by the heads of both agencies. Pursuant to subsequent discussions and negotiations handled by representatives of the solar energy program, approval for implementation of an ERDA study resulted and a modest effort has been initiated.

Question. If so, what are the time frame and scope of the investigation?

Answer. It is planned to conduct a joint NASA/ERDA SPS concept development and evaluation program. According to the detailed plan that has been developed, a comprehensive study of the SPS concept will be conducted beginning in mid-FY 1977 and culminating late in FY 1980 in a go-or-no-go decision on program continuation into a second major phase, NASA's so-called technology advancement (hardware development) phase. NASA and ERDA have mutually agreed that the three-year assessment will encompass three major functional activities, as follows: (a) systems (i.e., hardware) definition, (b) space-related technology, and (c) environmental, socioeconomic, and comparative evaluation. It has been further agreed that NASA will have principal responsibility for the work dealing with systems definition and space-related technology whereas ERDA will carry lead responsibility for assessments concerned with environmental factors, socioeconomic issues, and comparative evaluations.

The Division of Solar Energy (SOLAR) has been assigned overall responsibility and authority for directing ERDA's participation in the joint SPS program. Budgetary authority also resides with SOLAR. In conducting SPS-related activities, the SOLAR staff is assisted by technical representatives from ERDA's Division of Technology Overview (TO) and Division of Biomedical and Environmental Research (BER).

Major elements in the planned ERDA SPS-related program are outlined below:

- Assessment of Environmental Factors:
  - Terrestrial operations
  - Launch, flight, and recovery operations
  - Space operations
  - Microwave impacts
- Assessment of Socioeconomic Issues:
  - Resource utilization
  - Economics/energy balance
  - Institutional/international factors
- Comparative Evaluations:
  - Terrestrial alternatives to SPS
  - Comparison (methodology, data base, and comparative assessment)

At the present time, BER representatives are responsible for managing three ongoing contracts for preliminary assessments of specific needs to resolve issues related to microwave effects on human health; biota and ecosystems; the atmosphere; and navigation, communication, radioastronomy, and electronic devices.

Question. Is this research coordinated with the National Aeronautics and Space Administration?

Answer. Yes. This activity has been closely linked with the NASA program from the very start. All planning activities have been coordinated with NASA through the NASA Office of Energy Programs, and a similar pattern of interaction is expected to continue throughout the three-year implementation phase.

Senator STEVENSON. Our next witness is Mr. Grover Wrenn, Deputy Director for the Health Standards program of the Occupational Safety and Health Administration.

STATEMENT OF GROVER WRENN, DEPUTY DIRECTOR, HEALTH STANDARDS PROGRAMS, OCCUPATIONAL SAFETY AND HEALTH ADMINISTRATION, DEPARTMENT OF LABOR; ACCOMPANIED BY BENJAMIN W. MINTZ, ASSOCIATE SOLICITOR OF LABOR; AND JOHN O'NEILL, DIRECTOR OF THE OFFICE OF PHYSICAL AGENTS STANDARDS

Mr. WRENN. Thank you.

Senator STEVENSON. I would be happy to put your full statement in the record so you could summarize.

Mr. WRENN. With me this morning on my right is Mr. Benjamin Mintz, Associate Solicitor of Labor for Occupational Safety and Health. On my left, Mr. John O'Neill, Director of OSHA's Office of Physical Agents Standards.

In the interest of time, Mr. Chairman, since the agency has recently responded to the committee's request for information in advance of the hearing, and we have submitted a statement, I would be happy to dispense with the reading of that statement or even a substantial summary of it and submit to any questions you have.

Senator STEVENSON. Thank you. Are you going to dispense with all statements?

Mr. WRENN. I would be happy to do that. Perhaps it would be useful if I note briefly that the Occupational Safety and Health Act of 1970 created the Occupational Safety and Health Administration. Our broad charter is to establish standards and enforce them to provide for the safety and health of American workers.

Radiation, both ionizing and nonionizing, is but one of the many aspects of worker safety and health that OSHA deals with. Additionally, as you know and have heard in the testimony of other agencies appearing before the committee, there are many other programs relating to radiation safety and health in the workplace for which other agencies have long had some regulatory responsibility. Therefore, OSHA is but one part of the overall Federal and State regulatory activity in providing for radiation safety and health programs in the workplace.

The statement does treat in some detail the relationship between OSHA regulatory programs and those that exist under NRC in particular and at the State level under both OSHA and NRC agreement plans.

I think those are the principal aspects of the statement.

Senator STEVENSON. Do you believe that the standards for exposure to radiation that you have to enforce are adequate, that the standards were derived from an adequate data base and that they adequately address the hazards associated with all forms of exposure to radiation in the workplace?

Mr. WRENN. I am not confident that that is the case. First of all, the scope of our regulations as presently established is quite broad in that OSHA regulations apply to any and all sources of ionizing radiation exposure, whatever that source may be, especially to the extent that it is not subject to regulatory authority of the NRC. However, the standards—the substance of the regulations that we enforce is derived entirely from long-established regulations issued originally by the AEC, adopted then under the Walsh-Healey Public Contracts Act by the Department of Labor to apply to employees of Federal Government contractors and then adopted without change under the provisions of the Occupational Safety and Health Act from the Walsh-Healey Public Contracts Act.

I would say to you that the substance of those standards has, at least in the experience of OSHA, not undergone review for the adequacy or protections they afford during the 6 years we have been in existence and of course many years prior to that while they were administered by other agencies.

Senator STEVENSON. Why haven't they been reviewed? How did OSHA accept the adequacy of them in the first place?

Mr. WRENN. The Occupational Safety and Health Act provided under section 6(a) of the act that during the first 2 years that the act was in effect the Secretary of Labor would promulgate as Federal Occupational Safety and Health Standards without administrative rulemaking all existing Federal safety and health standards and national consensus standards. That was the manner in which the Congress envisioned the agency would establish its initial body of safety and health standards on which to begin operation. As such, the substantial body of radiation safety standards that had been developed under the AEC and existed under the Department of Labor as part of the Walsh-Healey Safety and Health Standards were adopted without comment and without review.

That was the case with the entire body of initial safety and health regulations established by OSHA.

Since that time, Mr. Chairman, the very limited technical resources of OSHA in the standards-setting area have been largely consumed in focusing on new and more recently identified worker health hazards, particularly chemical carcinogens such as vinyl chloride, asbestos, arsenic, benzene and other such substances.

Simply as a matter of priorities, we have not had the luxury, so to speak, of looking backward at that initial body of regulations that we adopted when the act was first promulgated.

I will indicate to you, however, in recent efforts to expand the professional capabilities of the agency in the standards-setting area, particularly in the health area, we have established a new office of physical agents standards which is just at this moment beginning to be staffed. One of the major purposes of that office will be to review our existing body of standards for both ionizing and nonionizing radiation and in cooperation with our sister research agency, the National Institute for Occupational Safety and Health, from whom you will hear later, review existing evidence as to the adequacy of our standards and move as necessary to amend them.

Senator STEVENSON. Are the resources of NIOSH adequate?

Mr. WRENN. I think they will be speaking on that issue in their testimony.

Senator STEVENSON. For review of the standards?

Mr. WRENN. I have no reason to believe that they are not.

Senator STEVENSON. How long will this review take?

Mr. WRENN. We have placed little or no demands on them in that area because as I mentioned, the focus of our rulemaking activity has just not been directed toward the subjects of radiation in recent years.

Senator STEVENSON. Have you ever inspected workers exposed to radiation in a coal-fired generating plant?

Mr. WRENN. I seriously doubt it. I have looked at our records of enforcement activity at the Federal level under our radiation safety standards and the number of such inspections is limited. I did not identify the kinds of facilities in which those inspections were conducted. I would doubt very seriously.

Senator STEVENSON. You would have the authority to do so; would you not? Wouldn't that be within your jurisdiction?

Mr. WRENN. If it were a private enterprise, yes, it would be.

Senator STEVENSON. You noted in your statement that OSHA had conducted 28 inspections for ionizing radiation health hazards during fiscal 1976. That confirms what you are saying. It certainly sounds like a minimum effort. What kind of inspections were those?

Mr. WRENN. Those were most likely inspections of a general occupational health nature in a work place during the course of which some question of radiation protection was discovered. It is possible that the inspection was specifically related to a question of radiation safety, but with the knowledge of our field activities, generally, I would expect that those questions would have arisen in an inspection of a broader scope than simply radiation.

Senator STEVENSON. Can people who operate airport baggage scanners and passengers exposed to those scanners be assured that they are not being exposed to excessive ionizing radiation? Do you take steps to protect the people who operate those scanners?

Mr. WRENN. The Occupational Safety and Health Regulations would apply to employees engaged in the inspection processes. They would not apply in a consumer protection sense to passenger personnel. I did have an opportunity to review the statement that will be presented later by the National Institute for Occupational Safety and Health. I believe they refer to a recent survey of such baggage inspection equipment which they assisted in evaluating the safety of.

Senator STEVENSON. What about OSHA? Did it inspect these facilities?

Mr. WRENN. Our regulations could be applied in that area. Again, I know of no specific circumstances when we have done so. I suspect as a matter of practice at the present time, because of our focus on a number of other health issues, that it would not likely—we would not likely conduct such an inspection except in response to an employee complaint.

Senator STEVENSON. Well, this committee has been receiving employee complaints. One employee that we are aware of has questioned her employer. She questioned him repeatedly about acceptable radiation levels but never received an answer. The employees who man these scanners are given no advice or warning about the level of radiation to which they are exposed. They are given dosimeter fountain pens, but they apparently get mixed up and different persons wear the same pens, so the pens reveal little if anything about each person's exposure.

They receive no indication of the levels of radiation to which they have been exposed. The employees in the early stages of pregnancy receive no special attention.

What you are saying then is that they have to complain before OSHA will protect them?

Mr. WRENN. I am saying as a matter of practice, because of the limited number of health compliance officers that we currently have for the entire country, the number of work places that we have responsibility for conducting inspections in, and the current focus of the agency on such health hazards as lead and mercury and chemical carcinogens that is not likely in the normal course of events that we would inspect for that hazard, although we have very distinct procedures for responding to employee complaints.

In the normal course of events, were we to receive an employee complaint about such matters, we would undoubtedly respond with an inspection.

Senator STEVENSON. Don't you think in the normal course of events this is something that should be looked at even with your limited resources?

Mr. WRENN. Mr. Chairman, I could agree to an affirmative response to that question about a number of subjects in the occupational health field, including ionizing radiation.

Senator STEVENSON. Well, we would urge you to do that and would be very interested in finding out what the results of your look are.

We have heard of a NIOSH report which apparently concludes that as many as four out of five industrial radiation incidents go unreported. Is OSHA attempting to coordinate with BRH's incident radiation registry to rectify this situation?

Mr. WRENN. We have a close working relationship with the Bureau of Radiological Health. We do receive the incident reports from BRH. I think we share that general perception that even with specific reporting requirements, there is substantial underreporting of such incidents.

Senator STEVENSON. The EPA has indicated that OSHA won't cooperate with the Interagency Task Force on Occupational Exposure Standards. How do you respond to that?

Mr. WRENN. I am sorry. I didn't understand your question.

Senator STEVENSON. Apparently EPA has indicated that OSHA would not cooperate with an Interagency Task Force on Occupational Exposure Standards. That task force is reviewing and adopting standards. If this is true, why doesn't OSHA cooperate?

Mr. WRENN. Mr. Chairman, I am unaware of any opportunity which OSHA has had to cooperate with the EPA in which we declined to do so. I would be glad to look into that.

Senator STEVENSON. I would appreciate that.

Thank you very much.

We have more questions, but we will take the liberty of following up in writing.

[The statement follows:]

STATEMENT OF GROVER WRENN, DIRECTOR OF HEALTH STANDARDS PROGRAMS FOR THE OCCUPATIONAL SAFETY AND HEALTH ADMINISTATION

Mr. Chairman and members of the committee, I thank you for the opportunity to appear today and discuss the response of the Occupational Safety and Health Administration (OSHA) to the challenge of controlling workplace radiation hazards. Accompanying me today is Benjamin W. Mintz, Associate Solicitor of Labor for Occupational Safety and Health.

OSHA has the responsibility of assuring, so far as possible, that all employees in the Nation are provided with safe and healthful working conditions by their employers. Under the Occupational Safety and Health Act of 1970, covered employers have the general duty to provide a place of employment free from recognized hazards likely to cause death or serious physical harm. In addition, the Act provides a specific obligation that such employers comply with job safety and health standards issued by OSHA. In administering this law, OSHA conducts workplace inspections to assure compliance with these obligations. When OSHA's compliance officers discover violations during an inspection, employers may be issued appropriate citations, civil monetary penalties may be proposed and periods for correcting the alleged violations are established.

Any of thesse may be contested before the Occupational Safety and Health Review Commission, an independent adjudicatory body established to hear such appeals, OSHA also pursues a program of consultation, information, and education to assist and encourage those employers seeking to comply with the law.

Section 18(b) of the OSH Act affords each State the opportunity to submit a plan which would allow the State to assume responsibility for occupational safety and health matters. The State's program must be at least as effective as the Federal program. OSHA closely monitors the implementation and progress of each State plan to assure its continued effectiveness, and may withdraw its approval and resume Federal jurisdiction if the State plan fails to fulfill its commitment to implement and administer an equally effective program. Presently, 24 States are implementing plans which have been approved by the Secretary of Labor under section 18(b).

In discussing OSHA's specific responsibility for workplace radiation hazards, let us first examine the scope of the problem. In general, ionizing radiation is any radiation capable of producing ions by interaction with matter. X, gamma, alpha, beta and neutron are the radiation types of primary concern to OSHA because of their frequent presence in the occupational environment. The potential for exposure to ionizing radiation is especially great among certain workers including medical and dental personnel, industrial radiographers, food processors, materials handlers and equipment service personnel.

While the effects of high level exposure have been known for years, the effects of lower level radiation have not fully been observed. The body's response to the assault of radiation differs from one individual to another depending on a number of factors, including the tissues affected, one's age at the time of exposure and the irradiation energies to which one is exposed. OSHA, therefore, recognizes the desirability of establishing standards which adequately assure employee protection.

Section 6(a) of the OSH Act provided for the adoption as the OSHA standards of any established Federal standards which were in force at the time of enactment. OSHA adopted as radiation standards, and continues to enforce, those promulgated under the Walsh-Healey Public Contracts Act. The OSHA radiation standards are found at 1910.96 and 1910.97 of Title 29 of the Code of Federal Regulations. As further background, these Walsh-Healey standards were modeled on those developed by the Atomic Energy Commission whose authority is now vested in the Nuclear Regulatory Commission (NRC) and the Energy Research and Development Administration (ERDA). Therefore, OSHA's radiation standards and those of NRC are essentially the same.

The NRC and OSHA standards, although virtually the same, do not, however, apply to the same situations. NRC's statutory authority is limited to coverage of those radiation sources emanating from three categories of material known as source, byproduct, and special nuclear materials. A number of so-called other sources of radiation, for example, X-ray machines, naturally occurring materials such as radium, electron miscroscopes, particle accelerators and airport baggage scanners, are outside the purview of NRC.

The OSH Act comprehensively covers every employer who is engaged in a business affecting commerce and who has one or more employees. The Act contains no express limitations on this coverage nor any express general exemptions. However, it does contain provisions designed to avoid duplication of effort between OSHA and other agencies with statutory authority to promulgate standards or regulations affecting occupational safety and health. Under section 4(b)(1) of the Act, OSHA does not apply to working conditions addressed by other Federal agencies standards or regulations affecting occupational safety and health. Thus, OSHA applies its requirements, including its radiation standards, to those radiation working conditions not addressed by NRC's standards. Specifically, this means that OSHA applies to working conditions where employees are exposed to "other sources" since there is neither coverage nor applicability over these sources under NRC standards.

While the jurisdictional lines between OSHA and NRC are clear, another jurisdictional arrangement involving the States requires some explanation. Even before the enactment of OSHA, certain States entered into licensing agreements with the AEC pursuant to section 274 of the Atomic Energy Act of 1974, as amended (42 U.S.C. 2021), under which it was determined that these "agreement States" would be allowed, to regulate "other sources" of radiation in the interest of providing workers with the fullest protection. OSHA has allowed these States to continue their regulation of these "other sources" provided the Assistant Secretary of Labor determines that the States' programs are compatible with the OSHA radiation regulations. In these States employers registered and licensed under a State-NRC agreement program are considered to be in compliance with OSHA radiation standards. The Assistant Secretary's determination is facilitated by an annual letter from the Nuclear Regulatory Commission to the Assistant Secretary of Labor setting forth assurances that the States' programs are compatible. OSHA's current rationale for continuing such an approach is the preservation of State jurisdiction in areas which the States have long been regulating in a manner consistent with Federal radiation standards. In addition to regulating "other sources" because they have an agreement with NRC, States may also be operating an OSHA approved State plan which must contain radiation standards identical to or at least as effective as Federal OSHA standards.

Such State OSHA standards likewise contain provisions for accepting employer compliance with State-NRC agreement regulations as compliance with State OSHA radiation standards. Often States utilize the same technical staff for "NRC agreement" and "OSHA State plan" radiation enforcement through a system of referrals.

Another Federal agency with radiation safety and health responsibilities is the Energy Research and Development Administration. ERDA controls facilities which are government owned and contractor operated (GOCO's). The Atomic Energy Act expressly provided for the promulgation of standards to protect the workers in these government owned facilities from workplace hazards including, but not limited to, radiation hazards. To implement that statutory authority under the Atomic Energy Act, AEC (now ERDA) agreed to issue all the OSHA standards. Those standards are now applicable to all private employers working in GOCO facilities regulated by ERDA. By operation of law ERDA, not OSHA, is responsible for the enforcement of these standards. These circumstances were recognized in a letter between the Secretary of Labor and the AEC in 1974.

One final Federal agency with which OSHA shares concern for radiation hazards is the Food and Drug Administration's Bureau of Radiological Health (BRH). A Memorandum of Understanding between the two agencies was signed in 1974 in which OSHA and BRH agreed to establish uniform standards for regulating electronic products, our concern being those used in the workplace. Also included in that agreement are provisions which require that each agency notify the other should any suspected violations of the agency's standards be discovered during routine inspections.

OSHA radiation compliance activity during fiscal year 1976 consisted of 28 inspections for ionizing radiation as well as 25 microwave inspections and four inspections involving lasers.

OSHA will continue to work with the Federal and State agencies which I have mentioned in order to ensure that workers are afforded protection from the hazards of radiation. I will now be happy to answer any questions the Committee may have.

[The following information was subsequently received for the record:]

U.S. Department of Labor,
Occupational Safety and Health Administration,
Washington, D.C., December 1, 1977.

Hon. Warren G. Magnuson,
Chairman, Committee on Commerce, Science and Transportation, U.S. Senate, Washington D.C.

Dear Mr. Chairman: This is in response to your September 13, 1977, letter in which you requested that I answer a number of additional questions following the Committee's oversight hearings on radiation health and safety. My answers to these questions are enclosed and, as you requested, I have submitted five copies of my responses to your Committee staff under separate cover.

Please excuse the delay in responding to your request. If I can be of further assistance, please contact me.

Sincerely,

Grover Wrenn,
Director, Health Standards Programs.

Enclosure.

Question 1. Please submit to the Committee a time schedule for the proposed review by OSHA of ionizing and non-ionizing radiation standards and the date when revised standards are expected to be issued.

Response. The process of reviewing existing standards for ionizing and non-ionizing radiation is a continuing one, as it is for all safety ad health standards, and the Occupational Safety and Health Administration (OSHA) is currently performing staff work on its ionizing and non-ionizing radiation standards. However, at the present time, there is no specific timetable for the issuance of revised radiation standards. OSHA must set priorities which ensure that the greatest number of workers receive protection from the most serious occupational safety and health hazards. OSHA is currently attempting to establish a realistic schedule for the completion or revision of those standards which deserve the greatest attention. A listing of the safety and health standards which merit the highest priority for future rulemaking was recently submitted to the U.S. District

Court for the District of Columbia. This listing was submitted as part of a report required by the Court in *Usery* v. *National Congress of Hispanic American Citizens*. The listing reflects our best judgment of OSHA's rulemaking priorities, and a copy is enclosed for your information. The exclusion of radiation standards from this listing in no way is meant to imply that OSHA considers the hazards of radiation unimportant. Rather, it simply reflects our belief that OSHA's resources may be better utilized by concentrating our standards-writing efforts in areas where either no standards exist, or where existing standards do not provide adequate protection from the hazards they address.

Coverage of workers exposed to the hazards of radiation continues to be provided by a comprehensive OSHA ionizing radiation standard under 29 CFR 1910.96. In addition, OSHA has requested that the National Institute for Occupational Safety and Health provide its recommendations concerning a future OSHA standard for microwave radiation and other forms of electromagnetic radiation.

HEALTH STANDARDS PRIORITIES OSHA WORKPLAN FOR JULY 1977 TO JANUARY 1978

Hazard domain	Priority factors (exposure; effects; evidence)	Project status
Diving	2,000 to 2,500; decompression sickness and trauma.	Published.
Arsenic[1]	10,000; lung cancer; scientific literature and research; animal studies; epidermiology.	Draft final standard under agency review.
Cancer policy[1]	Millions; special attention to serious health problems.	Draft proposal under review by solicitor.
Labeling[1]	Millions; right to know workplace hazards	Research continuing.
Cotton dust[1]	700,000; bysinosis, chronic obstructive, lung disease; scientific literature and research; epidermiology.	Record of rulemaking being evaluated prior to preparation of final draft standard.
Benzene[1]	200,000 to 1,000,000; leukemia, blood dyscrasis; scientific literature and research; animal studies; epidemiology.	ETS issued May 1977; hearings July 1977; final standard November 1977.
Standards completion project—Toxic substances.	Millions; establish permissible exposure limits.	6 ketones; draft of single standard for 400 toxic substances under review.
Lead	1,200,000 to 5,300,000; lead intoxication, "subclinical" effects, susceptible groups, rate retention; scientific literature; animal studies; epidemiology.	Record of rulemaking being evaluated prior to preparation of draft final standard.
Emergency temporary standard (ETS).	Unknown; serious health effects; as available.	To answer unscheduled crisis as it evolves.

HEALTH STANDARDS PRIORITIES OSHA WORKPLAN FOR JANUARY 1978 TO JULY 1978

Beryllium	Several thousand; beryllium disease, lung disease; scientific literature and research; animal studies; epidemiology.	Proposal ready; hearings scheduled to begin Aug. 16, 1977.
Noise	13,000; noise-induced hearing loss; scientific literature and research; animal studies; epidemiology.	Proposal ready (need staff assistance to evaluate record).
Pesticides	360,000 (manufacturing and fabrication); attacks various body functions, lungs, etc.; scientific literature and research; animal studies; epidemiology.	Research continuing.
Skin dermatitis	Millions; dermatitis sensitization absorption/systemic toxicity; workers' compensation; lost work days; scientific literature; medical experience.	Advisory commission being reformed.
Abrasive blasting	84,000 to 200,000; acute silicosis/other toxic dusts; scientific literature and research; animal studies; epidemiology.	Draft proposal being developed.
Confined spaces	Millions; suffocation or exposure by inhalation to toxic gases and vapors combined with physical hazards of difficult entry/egress; scientific literature and research; animal studies; epidemiology.	Research continuing.
Chromates	15,000 to 25,000; cancer; scientific literature and research; animal studies; epidemiology.	Draft proposal ready for agency review.
Chlorinated solvents (trichloroethylene [TCE], perchloroethylene [PCE] methyl chloroform).	Millions; narcosis (acute) possibly carcinogenic; scientific literature and research; animal studies; epidemiology.	Proposal for TCE published Oct. 20, 1975.
Emergency temporary standard (ETS).	Unknown; serious health effects; as available.	In response to emerging evidence.

[1] Proposal or final rule will be published by January 1978.

Notes: (1) Health standards priorities will be evaluated every 6 mo since rapid changes in OSHA knowledge of hazards occur frequently. Resources have been earmarked above for a high-priority substance which may be handled as emerging temporary standards (ETS). (2) New health standards for sulfur dioxide, TDI/MDI and asbestos will be reconsidered at this time.

Question 2. What changes do you contemplate in those standards? What will be included in your data base?

Response. While OSHA has established no specific timetable for revision of its radiation standards, staff work is being performed to study the scope of any possible changes in these standards. A discussion of these efforts follows.

A. Ionizing Radiation

1. Changes

A revision of OSHA's ionizing radiation standard, 29 CFR 1910.96, is under development at the present time. One purpose of this effort is to achieve consistency in the protection provided by OSHA and other Federal agencies. It is anticipated that certain technical definitions would be revised to conform with those now commonly accepted in the professional community. In consideration of the efforts of both national and international standards activities, the issue of whether or not to accept a black color radiation warning symbol (as an alternative to the purple symbol) on a yellow background is being considered. OSHA's efforts at revising its ionizing radiation standard also include the consideration of: new labeling provisions applicable to x-ray equipment; a radioactive materials inventory reporting provision; requirements for specific radiation protection interlocks and posting requirements for facilities containing x-ray equipment; new radiation survey requirements; and some changes to the reporting and record-keeping requirements. It is anticipated that property damage alone will no longer be a reason for making a report to OSHA under any future revision of the standard.

As with practically all radiation protection standards and guidance, including those of the Federal Radiation Council and the former Atomic Energy Commission, the primary data base is composed of the recommendations from the National Council for Radiation Protection and Measurements and the International Commission on Radiation Units and Measurements. Secondary data bases include regulations and standards of the Nuclear Regulatory Commission, the Food and Drug Administration, the American National Standards Institute (ANSI), the Department of Transportation, and the model regulations of the Conference of State Radiation Control Program Directors.

B. Laser Radiation

1. Changes

OSHA's current standard for laser radiation, 29 CFR 1926.54, is applicable solely to the use of lasers in the construction industry. Our current efforts to revise this standard would extend its applicability to general industry, shipbuilding, and agriculture. Provisions on labeling, eye protection, posting, and interlocks would be required as the relative laser radiation hazard potential increases.

OSHA is reviewing a number of reports, suggestions, standards and recommendations on laser safety and bioeffects in the study of this standard. The primary data base is the ANSI laser safety standard. A number of standards are also being reviewed and analyzed for rationale and effectiveness in providing the intended degree of safety. These include the laser standards and recommendations prepared by the U.S. Army Environmental Hygiene Agency, the British standards organizations, and the Bureau of Radiological Health (BRH). We are also utilizing the Laser Classification Guide, which was prepared by the U.S. Army Environmental Hygiene Agency and published by the National Institute for Occupational Safety and Health. This guide, prepared at OSHA's request, contains technical information on approximately 2,500 different model lasers that have been manufactured.

Question 3. On page 75 of the transcript, Dr. Rowe, Deputy Assistant Administrator for Radiation programs for EPA, mentioned an interagency group which examines appropriate standards for occupational radiation exposures. There is some question as to the extent of cooperation by OSHA and other agencies in this effort. Please explain any misunderstandings EPA and OSHA are having in working together within this interagency framework. What caused them? Have they been resolved?

Response. The Environmental Protection Agency (EPA) has a broad mandate to protect the general public and the environment from radiation exposures. OSHA, on the other hand, has jurisdiction over occupational radiation exposures from such sources as x-ray machines and accelerator produced and naturally occurring radioactive materials. To the extent permitted by its statutory authority and resources, OSHA has cooperated with the EPA Interagency Committee to protect workers from radiation hazards. Despite this cooperation, there have been apparent limitations to the effectiveness of this arrangement.

Early this spring, OSHA, EPA, the Consumer Product Safety Commission (CPSC), and the Food and Drug Administration (FDA) agreed that improvement in the overall coordination by regulatory agencies responsible for safeguarding worker and public health was needed. In early August, these agencies, working in concert, began planning to streamline their regulatory processes and to maximize their resources. As a result of this effort, on September 26, 1977, OSHA, EPA, CPSC and FDA entered into an interagency agreement relating to the regulation of toxic and hazardous substances which includes radiation control.

The objectives of this agreement are threefold: (1) to make the most efficient use of resources, (2) to achieve consistent regulatory policy, and (3) to improve the protection of the environment and of worker and public health. To meet these objectives, the agencies will coordinate: regulations where a hazard can be most effectively controlled by joint participation; compliance and enforcement procedures and policies; research and development policies; methods of obtaining, analyzing, storing, and exchanging information which could be of mutual interest; and public communication and education programs. Furthermore, the four agencies have established interagency communications channels to facilitate the exchange of information and to explore options for increasing cooperation and coordination.

Under this interagency agreement, a Regulatory Development Workgroup has been formed to study and make recommendations about regulatory problems common to two or more of the agencies. One of the topics to be studied by the workgroup is ionizing radiation, and a specific subgroup has been formed for this purpose with the Food and Drug Administration as the lead agency.

Question 4. Are OSHA's radiation protection guides merely advisory or are they mandatory? What is the status of the *Swimline Corporation* case?

Response. Section 6(a) of the Occupational Safety and Health Act of 1970 (the Act) provides that during the first two years following the effective date of the Act, the Secretary of Labor shall ". . . promulgate as an occupational safety and health standard any national consensus standard . . . unless he determines that promulgation of such a standard would not result in improved safety and health. . . ." One national consensus standard incorporated under section 6(a) was the American National Standards Institute (ANSI) C95.1–1966, which was promulgated as OSHA's non-ionizing radiation standard, 29 CFR 1910.97. The term "radiation protection guide" contained in the OSHA standard, therefore, had its source in the ANSI standard.

29 CFR 1910.97(a)(1)(iii) defines "radiation protection guide" as the "radiation level which should not be exceeded without careful consideration of the reasons for doing so." In the *Swimline Corp.* case, an administrative law judge for the Occupational Safety and Health Review Commission (the Commission) ruled that 1910.97(a)(2)(i), which sets forth the radiation protection guide limits, is advisory rather than mandatory because 1910.97(a)(1)(iii) states that the limits "should" not be exceeded. The Secretary of Labor had originally requested that the Commission review this case, but subsequently withdrew this request since it was likely that 29 CFR 1910.97(a)(1)(iii) could not have been enforced in this particular case. The administrative law judge's decision thus became a final order of the Commission.

1910.97(a)(1)(iii) specifies that the employer is not required to follow the "radiation protection guide" as long as "careful consideration" is given to reasons for deviating from the guide. No specific criteria have been established as to what constitutes "careful consideration." In *Swimline*, the employer established "careful consideration" criteria which were not rebutted by the Secretary. Had the Secretary determined that the employer failed to follow the radiation protection guide without giving "careful consideration," a citation for violating 29 CFR 1910.97(a)(2)(i) would have been proper.

It should be emphasized that the Secretary's position in the *Swimline* case was based upon the specific facts of that situation not upon the word "should" contained in the standard. It is the Department of Labor's position that "should" standards are mandatory. This position is derived from the definition of an OSHA standard (section 3(8) of the Act) and the mandatory duty of all employers to comply with such standards (section 5(a)(1) of the Act).

Question 5. Are you aware that NIOSH field studies indicate that 75 percent of the workers using radio frequency sealing and heating equipment were found to be exposed to radiation levels higher than the present occupational standard? When and how did you receive such information from NIOSH? How have you responded to these findings? What is currently being done to protect these workers?

Response. OSHA has received no information from the National Institute for Occupational Safety and Health (NIOSH) to indicate that there are adverse health effects associated with the use of radio frequency radiation equipment at the levels of exposure presently encountered. Although OSHA does recognize the fact that the proliferation of industrial radio frequency equipment constitutes a potential occupational health problem, OSHA must obtain more complete bioeffect and exposure data as a basis for the development of an occupational health standard. These data will help us facilitate our evaluation of occupational exposures to radio frequency radiation; and to this end OSHA has requested that NIOSH provide us with its recommendations, perhaps in the form of a criteria document. OSHA could then use these recommendations in the promulgation of a future radio frequency standard.

Question 6. Laser devices are finding increasing use in many areas of our society, including the workplace. How extensive are OSHA's activities in this area?

Response. As indicated in our response to Question 2, OSHA currently has standards applicable to the use of lasers in the construction industry in 29 CFR 1926.54. These standards provide for qualified laser operators; mandates safe work practices, including personal protective equipment, warning signs and equipment labelling; and set limits for employee exposure. During Fiscal Year 1976, 74 violations of 1926.54 were cited by OSHA.

While staff work has begun on a new laser standard with a wider range of industrial applications, no specific date for promulgation of this new standard is yet available.

Question 7. How serious is the problem of excessive exposure to ironizing radiation for medical and dental personnel, industrial radiographers, food processors, materials handlers, and equipment service personnel? Are these people being routinely monitored to determine cumulative radiation dose, and to allow follow-up studies of future health effects?

Response. OSHA ionizing radiation standards (29 CFR 1910.96) require that all employers covered by the Occupational Safety and Health Act of 1970 (the Act) take precautionary measures to ensure that no employee is overexposed to ionizing radiation in the workplace. These measures include the requirement that personal monitoring equipment be provided for each employee who enters a restricted area under such circumstances that he receives, or is likely to receive, a dose in any calendar quarter in excess of 25 percent of the applicable maximum permissible exposure limits. 1910.96 also mandates even stricter monitoring requirements for individuals under 18 years of age, and establishes detailed reporting procedures to be followed by employers whenever any overexposures do occur.

The problem of overexposure to ionizing radiation within occupational groups, such as health care and food processing, is very difficult to assess. Overexposure data, to the best of our knowledge, is not ordinarily collected or classified by occupational categories. However, data collected by the Nuclear Regulatory Commission, the Armed Forces and certain State agencies indicate that the vast majority of employees monitored for exposure to radiation are within existing exposure limits.

Question 8. Does OSHA have responsibility for protecting research students and faculty at universities employing radiation devices such as x-ray machines and lasers? If so, how is this responsibility being carried out? If not, whose responsibility is this?

Response. While OSHA comprehensively covers all private employers, Congress included section 4(b)(1) in the Act to avoid duplication of effort among Federal agencies. Section 4(b)(1) provides, in effect, that the Act may apply to all working conditions except those particular working conditions for which another Federal agency promulgates enforceable standards affecting occupational safety and health. But, even under the limitations of section 4(b)(1), the Act applies to all covered employers using x-ray and laser equipment since no nother Federal agency has preempted OSHA from applying to such equipment. The Act covers all employers, except Federal, state and local governments. Therefore, all covered employers, including private universities, must comply with OSHA requirements related to job safety and health protection for all employees utilizing x-ray and laser equipment.

In certain states OSHA indirectly provides job safety and health protection to public university employees through funding to the states. Section 18(b) of the Act allows each state to assume responsibility for its own occupational safety and health program. When a state program is determined by the Secretary of Labor to be at least as effective as the Federal program, it is Federally funded on a matching basis. Among other requirements of section 18, the state program must provide job safety and health protection for public employees in the state. Therefore, public university employees in those states with their own occupational safety and health programs approved by the Secretary of Labor would be provided protection.

Students, as the term is generally understood, are not considered "employees" for OSHA purposes. However, if a covered employer—a private college, for example—is in compliance with OSHA standards, the employer's workplace is thereby made safer for *all* those who occupy the workplace, whether they be faculty members (employees) or students. This would also be the case under state 18(b) programs applicable to both public and private universities in the state.

Question 9. Please document your assertion that the protection of airport baggage inspectors from excess radiation by x-ray scanners lies within the jurisdiction of OSHA. If this is the case, why have no inspections of this equipment been made?

During the oversight hearings, Senator Stevenson called your attention to the complaints he had received with respect to the safety of airport baggage scanner operators. These included: the improper use of dosimeter "fountain pens," rendering their measurement value meaningless; lack of action on the part of employer and OSHA despite repeated complaints and questions from one employee; and the complaint that pregnant employees receive no special attention. What has the agency done since these allegations were brought to your attention?

What plans do you have in the future to ensure that airport baggage scanners are not reaching excess levels of ionizing radiation and that safety standards are being observed?

Response. As discussed in our response to Question 8, section 4(b)(1) of the Act provides that the Act applies to all working conditions of private employers except those particular working conditions for which another Federal agency promulgates enforceable standards affecting occupational safety and health. While the Food and Drug Administration's Bureau of Radiological Health (BRH) does regulate the *emissions* from machines such as airport x-ray baggage scanners, its authority does not include the regulation of employee *exposure* to such equipment. Therefore, since no other Federal agency has preempted OSHA's application to the particular hazard of employee exposure to emissions from x-ray baggage scanners, the Act, by virtue of section 4(b)(1), applies to this particular hazardous working condition.

When the Federal Aviation Administration proposed that baggage scanning equipment be used for airport security purposes, OSHA assisted BRH in developing guidelines to eliminate unnecessary occupational and public exposure to emissions from these devices. These guidelines were published in the *Federal Register* on August 8, 1973. To evaluate the effectiveness of these guidelines, BRH inspected new equipment both at the manufacturing plants and at the airports after installation. The National Institute for Occupational Safety and Health, in response to a request for technical assistance, conducted studies to determine the effects of product design and work environment on employee exposure. OSHA, in its regulatory role, also responded to a number of employee complaints about scanning equipment.

Present regulations for the protection of employees from exposure to emissions from scanning devices do not differentiate between pregnant females and other employees. It is believed that no significant risk for pregnant employees exists when current standards for equipment design and operation and standards for worker protection are followed.

As priorities permit, OSHA will continue to inspect airports and evaluate employee exposure to x-rays as a part of baggage scanning activities. (OSHA inspection priorities are noted in the response to Question 10.)

Question 10. During the hearings you indicated that the 28 inspections which OSHA conducted in FY '76 for ionizing radiation hazards were made during the course of general health hazard inspections. Is it the opinion of OSHA that potential radiation health hazards are not considered a high enough priority to merit inspections for this purpose alone? Do you have plans to intensify your inspection program in this area?

By what criteria does OSHA determine the need for inspections? Are all facilities inspected periodically? How frequently are inspections made? How large an inspection force does OSHA have? How many inspectors are there from the states? Is the indicated number of inspections adequate to assure compliance with OSHA regulations and to assure the safety of workers? If additional funding were available to increase your inspection capability, what funds would be required to assure reasonable compliance?

Response. OSHA recognizes the great potential health problems associated with the use of radiation in the workplace. However, our limited inspection resources must be utilized in a manner which the greatest number of employees from the most severe hazards. In order to accomplish this end, the enforcement of standards is conducted within the context of a set of overall inspection priorities. These are, in order: response to reports of imminent danger; investigation of workplace fatalities and catastrophies; response to employee complaints of workplace hazards; generally scheduled inspections directed to workplaces in industries with known health hazards or high injury frequency rates; and areas of special emphasis. These priorities are designed to focus the Agency's attention on the most serious threats to worker well-being.

At our current rate of inspection, OSHA's 1435 Federal compliance officers would inspect about 2 percent of the nation's workplaces per year.

There are also 998 state inspectors conducting investigations in the 25 states or jurisdictions with their own occupational safety and health programs. From these figures, it is clear that OSHA must rely heavily on voluntary compliance of employers to assure safe and healthful workplaces. Although additional personnel would undoubtedly result in an increase in the number of inspected workplaces, it would be impossible to give a realistic figure of how many inspectors we require to assure "reasonable compliance."

Question 11. You agreed that as many as 80 percent of industrial radiation incidents go unreported. In order to encourage reporting of radiation incidents, do OSHA and BRH need additional authority to assess stronger sanctions against non-complying employers? What other measures should be taken to encourage compliance with reporting producers?

Response. The Agency feels that the Act provides sufficient sanctions against employers who do not comply with OSHA's regulations dealing with recordkeeping and reporting requirements. OSHA may impose civil penalties of up to $1,000 for other-than-serious violations and up to $10,000 for willful or repeateed violations of its recordkeeping and reporting regulations. As a further safeguard, section 17(g) of the Act provides that "Whoever knowingly makes any false statement, representation, or certification in nay application, record, report, plan, or other document filed or required to be maintianed pursuant to this Act shall, upon conviction, be punished by a fine of not more than $10,000 or by imprisonment for not more than six months, or by both."

Apart from recordkeeping, the Act contains other sanctions. Penalties of up to $1,000 per day may be imposed on employers who fail to correct violations discovered during an OSHA investigation. Mandatory civil penalties are applied in the case of serious violations; these may be up to $10,000. In imminent danger situations the Secretary of Labor may petition the district court to restrain an employer from continuing an unsafe practice. We feel that stronger sanctions than these are unnecessary.

OSHA's best method for assuring compliance with its regulations, in addition to its enforcement activities, is educating employers and employees about their responsibilities under the Act. One method OSHA employs in achieving this end is providing on-site consultative advice to employers through contracts with the states. This consultation, provided at the request of the employer, is available free-of-charge in 38 states and jurisdictions, and utilizes the states' personnel as consultants. Under this type of program, employers may discover problems in their workplaces and learn exactly what their responsibilities are under the Act.

OSHA also provides educational assistance to employers and employees through special programs designed to assist in the recognition, avoidance and prevention of unsafe and unhealthful working conditions, including those hazards posed by radiation. Two current training programs, for example, include radiation hazards as part of their curricula whenever the target audience may be exposed to radiation in the workplace. One of these programs is designed for apprentices and the other for union officials.

Question 12. In your prepared comments, you state that "OSHA also pursues a program of consultation, information, and education to assist and encourage those employers seeking to comply with the law." What is the current funding level for this program and what fraction of the business community does it reach? What efforts are being made to improve this program?

Response. During Fiscal Year 1977, OSHA budgeted approximately $1 million for education purposes. At this funding level only 0.1 percent of the employers and employees covered by OSHA received direct instruction under our educational programs. In order to reach more individuals, OSHA is developing a new strategy which will focus our educational efforts on employer and employee "peer group" organizations such as unions, trade associations, educational institutions, etc. rather than on employers and employees directly. The purpose of this strategy is to develop internal educational competence within these peer group organizations, and thereby increase the number of individuals receiving instruction. Additionally, OSHA's education budget for Fiscal Year 1978 has been raised to $3 million.

On-site consultation is currently available in 24 states and jurisdictions which operate their own safety and health programs under section 18(b) of the Act. Additionally, under section 7(c) (1) of the Act, OSHA has entered into contracts with 14 other states and jurisdictions in which their personnel are utilized to provide consultative advice free-of-charge to requesting employers. $12 million has been budgeted for these 7(c) (1) consultation programs for Fiscal Year 1978, and it is estimated that 20,000 consultative visits will be made. In order to further encourage states and jurisdictions to enter into 7(c) (1) contracts, the level of Federal funding for this purpose was recently increased from 50 to 90 percent of the program cost.

OSHA's public information program is operated by the national office, utilizing a variety of means, such as *Job Safety and Health* magazine, news releases and general information publications. The overall information budget for Fiscal Year 1978 is $670,000, a significant portion of which is used to inform employer and employee organizations about current occupational safety and health matters. The October 1977 issue of *Job Safety and Health*, for example, contains an article entitled "Radiation Safety in Industry." A copy of this magazine is enclosed for your information.[1]

Question 13. You state that under section 4(b) (1) of the OSH Act, OSHA "does not apply to working conditions addressed by other Federal agencies or regulation affecting occupational safety and health." If EPA were to promulgate an occupational exposure standard for non-ionizing radiation, would such a standard preempt OSHA's jurisdiction in the area?

Response. OSHA has interpreted section 4(b) (1) of the Act to mean that the Act applies to all working conditions except those for which another Federal agency promulgates enforceable regulations affecting occupational safety and health. Should EPA promulgate a standard for non-ionizing radiation, OSHA, by application of section 4(b) (1), would be preempted from applying to non-ionizing radiation hazards to the extent the particular hazard to employees in the workplace may be eliminated or reduced under the EPA standard. However, such a situation under section 4(b) (1) is not common, since EPA's statutory authority deals with problems affecting the environment and the public generally; OSHA's statutory authority is specifically directed to workplace hazards encountered in the employment context.

Question 14. Both BRH and EPA share with you some jurisdiction over either exposure or emission standards with respect to radiation emitted from medical equipment. How are these programs coordinated?

Response. An interagency agreement between OSHA, EPA, the Food and Drug Administration (including BRH) and the Consumer Product Safety Commission was signed September 26, 1977. The purpose of this agreement is to foster cooperative efforts among the participating agencies in their regulation of toxic and hazardous substances. Under this agreement, a Regulatory Development Workgroup has been formed to study and make recommendations about regulatory problems common to two or more of the agencies. One of the topics to be studied by the Regulatory Development Workgroup is ionizing radiation, and a specific subgroup has been formed for this purpose with the Food and Drug Administration as the lead agency. We are optimistic that the efforts of this subgroup will lead to more efficient use of the agencies' resources, the formation of consistent regulatory policies, and an improvement in the protection of the public's health and environment from the hazards of radiation.

---

[1] Retained in committee files.

An earlier memorandum of understanding between OSHA and the Food and Drug Administration provided for cooperative efforts between OSHA and BRH in establishing consistent Federal standards relating to electronic product safety, and in determining compliance with these standards. Although the cooperative efforts under this memorandum have been largely superseded by the more recent four-agency agreement, a number of contacts between OSHA and the BRH were made at the staff levels of both agencies.

Question 15. Dr. Harris of NIOSH indicated that OSHA has jurisdiction over uranium mining operations because it is a natural source of radiation. Please refute or support this statement, with citation to relevant statutes.

Response. Prior to the President's signing of the Federal Mine Safety and Health Amendments Act of 1977 on November 9, 1977, the Department of the Interior's Mining Enforcement and Safety Administration (MESA) had primary jurisdiction over safety and health conditions in uranium mining operations. The Federal Metal and Nonmetallic Mine Safety Act was the statutory basis for this authority.

Under the new Mine Safety and Health Amendments Act of 1977, MESA functions and personnel will be transferred to the Department of Labor on the effective date of the Act—March 9, 1978. Under the new law, a Mine Safety and Health Administration, within DOL, will have jurisdiction over mining, including uranium mines.

As noted in our response to Question 8, section 4(b)(1) of the Occupational Safety and Health Act of 1970 (the Act) was provided to avoid duplication of effort among the Federal agencies. Under section 4(b)(1), the Act applies to all working conditions of private employers except those particular conditions for which another Federal agency promulgates enforceable standards affecting occupational safety and health. Since uranium mining operations are covered by the regulations of another agency, OSHA, by application of section 4(b)(1), is largely preempted from applying to these operations.

Question 16. Does the Administration support proposals such as Senator Randolph's bill which would set federal minimum standards for licensing radiologic technicians?

Response. The Administration has not yet announced its views on Senator Randolph's bill—S. 1695, the Radiation Health and Safety Act of 1977.

Senator STEVENSON. Our next witness will be Dr. Elliott S. Harris, Director, Division of Biomedical and Behavioral Science, National Institute for Occupational Safety and Health, accompanied by a number of other witnesses.

STATEMENT OF DR. ELLIOTT S. HARRIS, DIRECTOR, DIVISION OF BIOMEDICAL AND BEHAVIORAL SCIENCE, NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH; ACCOMPANIED BY DR. WORDIE H. PARR, CHIEF, PHYSICAL AGENTS EFFECTS BRANCH; WILLIAM E. MURRAY, CHIEF, RADIATION SECTION; AND DR. ZORY R. GLASER, DIRECTOR, SPECIAL HAZARDS EVALUATION PROGRAM

Dr. HARRIS. Thank you.

Senator STEVENSON. Thank you.

Dr. HARRIS. I am afraid Dr. Glaser stepped out for a moment. He will be in shortly.

Mr. Chairman, I am Dr. Elliott S. Harris, Director of the NIOSH Division of Biomedical and Behavioral Science.

We are pleased to have been invited to discuss the NIOSH programs relating to occupational exposure to radiation. We have discussed in a separate letter the four specific questions Senator Magnuson raised in his letter of May 26.

The National Institute for Occupational Safety and Health, NIOSH, was established by the Occupational Safety and Health Act of 1970—Public Law 91-596. Prior to 1970, the predecessor organization of NIOSH operated under the general research authorities of the Public Health Service Act.

Between 1968 and 1971 a small portion of our resources were devoted to the radiation effort. Following passage of the act, NIOSH was given specific responsibility to develop recommended standards for exposure to a broad range of occupational hazards, including radiation. A radiation section was established in 1972 in the Physical Agents Effects Branch of NIOSH.

We do not have authority under the Radiation Control for Health and Safety Act of 1968—Public Law 90-602—which concerns the public health aspects of radiation emissions from electronic products.

However, under the Occupational Safety and Health Act, NIOSH has several vital functions related to occupational safety and health. These include the conduct of research programs, the performance of hazard evaluations, field studies, morbidity and mortality studies, the development of recommended standards, the dissemination of information to employers and employees, the provision of technical assistance, and the conduct of training and education programs. Many of these are concerned specifically with ionizing and nonionizing radiations.

The development of criteria documents as a basis for standards for occupational exposure to chemical and physical hazards is a continuing activity of NIOSH. These criteria documents are prepared for the purpose of recommending an occupational health or safety standard to OSHA within the Department of Labor, which is responsible for setting and enforcing standards to protect workers.

It is the goal of the Institute to identify the health effects produced by a substance or process and to recommend methods to evaluate and control the hazard. Before the documents are transmitted, they undergo extensive internal review and external review by management and trade associations, organized labor, academia, State and Federal agencies and professional societies.

More than 60 criteria documents recommending standards for occupational exposure have been transmitted to OSHA, including documents on hot environments and ultraviolet radiation. Documents involving consideration of worker radiation exposure planned for completion during fiscal years 1977 to 1981 include radio frequency—(RF)—and microwave radiation, infrared radiation, and ultrasonic radiation. In addition, a criteria document will be developed for welding and brazing processes, which have radiation exposure aspects.

One of NIOSH's major efforts mandated by Congress is the study of industrial carcinogens. Since it is well established that ionizing radiation induces cancer in man, NIOSH has initiated a study to survey the current knowledge of radiation-induced carcinogenesis. The information will assist us in estimating the potential carcinogenicity of the various forms of radiation and help to update the National Academy of Sciences 1972 summary report entitled, "The Biological Effects of Ionizing Radiation."

For the past decade, NIOSH and its predecessor organizations have been gathering, analyzing, and publishing epidemiologic data on the hazards to workers from radon daughter products present in the uranium mining and milling operations. It was this work which first identified the lung cancer problems among uranium miners. Efforts were initiated to control exposure, and a cohort of exposed workers is currently being followed as part of our surveillance activities. This research on uranium miners was also instrumental in developing field methods for measuring radon daughters, procedures for engineering controls, and medical monitoring procedures for the diagnosis of lung cancer.

NIOSH has provided technical assistance, upon request, in addressing problems from radiation-generating equipment. For example, because of employee concern for the possibility of excessive ionizing radiation exposure, the FAA and the ATA requested NIOSH to evaluate the potential exposure radiation hazards to airport personnel working with baggage X-ray inspection units. This is the study to which Mr. Grover Wrenn referred.

NIOSH performed this service, and concluded that the employee doses were well below the OSHA exposure standard, and that the radiation hazard was minimal.

A large part of NIOSH present and future radiation effort is the nonionizing area. Our efforts include programs on visible, infrared, optical, ultraviolet, laser, radiofrequency/microwave radiation and ultrasonic radiation.

NIOSH transmitted a criteria document on ultraviolet radiation—UV—to the Department of Labor in 1972. In addition to recommended occupational exposure standard, the document addressed environmental data, bioeffects, quantitative measurements, and protection and control measures.

I would like to add here as a comment that all our criteria documents do this. They not only address the standards, but they address control factors as well.

The UV portion of the spectrum is responsible for sunburn, and can produce eye damage. Prolonged exposure to UV radiation results in hyperpigmentation and the possibility of skin cancers. Another less common effect of ultraviolet radiation on normal skin causes the victim to develop freckling, depigmentation, precancerous tumors, basal and squamous cell cancers, and malignant melanomas. Welding arcs, certain sun tanning lamps, and industrial lamps and dryers can emit large amounts of UV radiation and have the potential of producing these effects in workers.

The following areas were identified in the ultraviolet criteria document as requiring further research effort: the lack of a portable survey instrument for evalulating UV hazards according to the recommended standard. That is a survey instrument which could be carried into the workroom and used there.

We also studied the need for research on the ocular effects over the wavelength range of 315 to 400 nanometers.

Portable UV monitors have been developed and are presently undergoing testing and evaluation. The National Bureau of Standards cooperated in developing an ultraviolet transfer standard, and in establishing at NIOSH a UV calibration facility. Research is also underway to determine UV thresholds for ocular effects in the 300–400 nanometer range.

In the infrared radiation area, although the near-IR portion of the spectrum has been implicated in the development of cataracts, threshold levels have not been established as a function of wavelength. NIOSH will soon initiate studies to assess eye damage resulting from exposure to such near-IR radiation. These data will be used to assist in the development of an occupational exposure standard.

In the area of lasers, in fiscal year 1968 we surveyed over 2,100 lasers in 200 occupational establishments in three States: Massachusetts, New Jersey, and California. The protocol included a review of the company safety program, and a "walk-through" survey of the laser operating area. The safety and engineering control procedures were found to be marginal or inadequate for 40 percent of the lasers in use.

In fiscal year 1975 NIOSH was requested by OSHA to prepare a compendium of lasers which would categorize lasers into one of five hazard classes specified in a recent draft of the OSHA proposed standard for exposure to lasers.

The report was compiled with the assistance of the U.S. Army Environmental Hygiene Agency and was published in 1976. The compendium contains technical data on 2,500 laser devices manufactured after 1963.

With the inception of the Federal energy conservation program, questions were raised about the health and safety implications associated with reduced illumination levels in the workplace. At the direction of the Secretary of HEW, NIOSH sponsored a symposium on the subject and invited experts in the field of illumination from the United States and Europe to present their views. Based on the information available, NIOSH concluded that the only effect on health from reduced illumination levels in the workplace would be an increased occurrence of eyestrain and that there was no evidence for any long-term permanent ocular damage.

With regard to safety, it was concluded that the standard used by the General Services Administration would not pose an additional hazard to worker health and safety. The proceedings of the symposium were published as a technical report.

Additional projects have been pursued which involve an integrated approach to evaluating optical radiation hazards. This includes the ultraviolet, visible, and IR spectrum.

We are performing a study in conjunction with the American Welding Society to examine hazards of the welding process. Optical radiation measurements have been made by NIOSH and the U.S. Army Environmental Hygiene Agency on the most common welding processes, under a variety of conditions.

We are also determining whether transparent welding curtains surrounding the welder protects his coworkers from harmful levels of optical radiation. At the request of the Newspaper Guild, we have performed surveys to measure the radiation emissions from the cathode ray tube of video display terminals used in a newspaper composition room where two young employees developed bilateral cataracts. The levels of optical and RF radiation measured were several orders of magnitude below the existing occupational exposure guidelines, and it has not been possible to establish that the cataracts are related to radiation emissions from these terminals.

NIOSH has developed a calibration and testing facility to assist in evaluating optical radiation hazards. This facility contains several standard sources and detectors for the calibration of laboratory and field instruments.

We have also initiated a quality assurance program to perform long-term studies on the stability, accuracy, and reproducibility of the instruments.

Continuing our discussion of the radiofrequency and microwave radiation area, workers are potentially exposed to RF and microwave radiation from a large number of sources and devices, including a large number of radio and radar transmitters, industrial drying, heat sealing and curing equipment, and certain medical research devices.

Consequently, NIOSH is planning a criteria document for occupational exposure to RF and microwave radiation. NIOSH is currently updating an extensive bibliography of world literature of the bioeffects of RF and microwave radiation.

Recent observations raise the question of this possibility of cancer induction by TACAN radar, which is extensively used for tactical air navigation. NIOSH was requested to investigate the work hazards associated with TACAN and TACAN repair at DOD facilities following the filing for worker's compensation of the surviving one of two TACAN repairmen who had been diagnosed as having carcinoma of the pancreas.

At none of the three survey sites did the measured levels of microwave or X-radiation exceed the currently accepted permissible exposure levels.

NIOSH is also considering performing a retrospective epidemiologic study to determine whether TACAN system repairmen exhibit an increased incidence of cancer of the pancreas, as well as carcinomas of other body sites.

NIOSH became aware of several problem areas in the radiofrequency radiation band, specifically 10–300 megahertz, in 1972. The first problem to be recognized was that employers often were unaware that they were using RF radiation in their facilities. This may have stemmed from the fact that the industrial uses of RF generators were not widely publicized, and little information was available on their uses.

For this reason, estimates of workers exposured to RF and microwave radiation vary from as few as 50,000 to as many as 21 million.

The second problem identified was that there were no survey instruments available with which "near zone" measurements could be made in the field. Third, little information was available on the biological effects at the radio frequencies used in industry.

The National Bureau of Standards laboratory in Boulder, Colo., has developed, under interagency agreement with NIOSH, RF-detection equipment capable of measuring the energy in the "near-zone" of the electromagnetic field, as is the case of the worker exposure situations we have studied.

A unique RF exposure and calibration facility capable of simulating near-field exposure conditions was also developed for NIOSH by NBS. This facility has been used to evaluate commercial monitoring instrumentation which manufacturers claim to be usable from 10 to 40 megahertz. Accurate measurement equipment and instrumentation, and standard survey techniques are essential for the monitoring and enforcement of RF and microwave exposure levels.

In our field studies 75 percent of the workers using RF sealing and heating equipment were found to be exposed to RF radiation levels higher than the present occupational exposure guideline. A majority of these workers were females of child-bearing age. Because recent literature indicates that exposure of pregnant animals to RF radiation may harm the fetus, we have started animal studies designed to determine threshold levels for effects from RF exposure.

Various NIOSH divisions provide support and training functions in the radiation field. NIOSH has been responsible for the calibration of instrumentation used by the OSHA compliance officers in inspections of the workplace. The Maintenance and Calibration Laboratory has established calibration procedures and techniques for ionizing radiation and microwave survey instruments. These instruments are routinely calibrated on a 12-month cycle. A radio frequency radiation calibration facility is in the final stages of development and will be completed by the end of 1977.

NIOSH presents short-term training courses in occupational safety and health as part of its responsibilities for manpower development. The courses provide the health professional with an overview of industrial hygiene and safety as well as specialized training to broaden the background of the practicing professional.

Two of the specialty courses address the safety and health problems associated with ionizing and nonionizing radiations. Course materials are available to any Federal or State agency and other interested groups. The general availability of these courses serves as a multiplying factor in enhancing the NIOSH role in training and manpower development.

Mr. Chairman, this concludes our overview of NIOSH's involvement in the occupational aspects of radiation health effects and worker protection.

If you have any questions, my colleagues and I will be glad to try to answer them.

Senator STEVENSON. Thank you, Dr. Harris.

You say that more than 60 criteria documents recommending standards for occupational exposure have been transmitted to OSHA. How many of these standards have been adopted by OSHA?

Dr. HARRIS. At the present time the ones on asbestos, vinyl chloride, coke oven emissions, and a group of 13 chemicals shown to be carcinogens, have been adopted. There are 10 to 12 currently in the rulemaking process. So we are talking about a handful that have been adopted, and 10 to 12 more in the rulemaking process.

Senator STEVENSON. Out of 60?

Dr. HARRIS. Out of 65; yes, sir.

Senator STEVENSON. What happens to the others?

Dr. HARRIS. They are still being reviewed within OSHA. OSHA must go through a public hearing process.

Senator STEVENSON. Does OSHA have the adequate resources with which to review these criteria documents?

Dr. HARRIS. I cannot address that. I do not know.

Senator STEVENSON. What are the major sources of exposure by workers to ultrasonic radiation?

Dr. PARR. There are a number of them which I could identify at this time. Probably one of the most widespread is the jet plane. The Navy has expressed concern about women flight directors for landing aircraft, some of whom may be pregnant.

Other groups include outside workers at airports. We have had a request from Pittsburgh to look into a situation where there is an increased number of cardiac or related problems.

Dr. HARRIS. Ultrasonic devices are used extensively in industry for cleaning and for welding. They are also used medically for diagnosis of cancers and for locating and determining the position of the human fetus. There are a wide number of uses for ultrasonics.

Senator STEVENSON. Are there standards and are they in force now with respect to ultrasonic radiation?

Dr. HARRIS. There are no standards for industrial use of ultrasonic radiation.

Senator STEVENSON. What about the research with respect to infrared radiation?

Dr. HARRIS. Infrared is used extensively for drying and heating purposes. It is used for everything from drying to lamination of wood.

Dr. PARR. I want to add that the welding process gives off ultraviolet, visible, and infrared radiation.

Senator STEVENSON. Are there standards in this instance?

Dr. HARRIS. No, sir.

Senator STEVENSON. What are the major sources of exposure to radiofrequency radiation?

Mr. MURRAY. There are numerous applications, based upon the ability of RF radiation to cause objects to heat. We do have a list of applications that we can enter into the testimony.

Senator STEVENSON. I would be glad to have it.

Senator STEVENSON. You say NIOSH is beginning studies to determine threshold levels for effects of radiofrequency exposure. How long are those studies going to take? Do the workers exposed in the meantime have any protection?

Dr. HARRIS. The studies are longtime studies. One does not expose a single animal and hope to get any usable results. These are going to be fairly extensive studies which will be repeated at a variety of wavelengths, and durations of exposure using phantom models, as well as animals. We anticipate that it will be a minimum of 3 to 5 years before we have usable results. In the meantime, there are no standards.

Senator STEVENSON. You say that field studies—your field studies, 75 percent of the workers using RF sealing and heating equipment were found to be exposed to RF radiation levels higher than the present guidelines?

Dr. HARRIS. That is right. These are guidelines, not standards.

Senator STEVENSON. Let us take microwave radiation. What are the principal sources of worker exposure to microwave radiation?

Mr. MURRAY. Again, we are talking primarily about heating and drying applications, in the food processing industry, textile industry, plastics industry, forest products industry, and others.

There are also ovens which are undoubtedly used in commercial establishments.

They are also used for medical diathermy.

Senator STEVENSON. Any standards yet in the case of microwave radiation?

Mr. MURRAY. The present OSHA regulation does cover the frequency range from 10 megahertz up to 100,000 megahertz. This includes both the radiofrequency radiation and the microwave radiation areas. We do not feel that the guidelines below 300 megahertz in the RF range has been studied adequately to evaluate the possible human effects so as to assume that the guideline is valid. In fact, measurement in terms of power density using units of milliwatts, in which the standard is written is meaningless in the radiofrequency range.

Senator STEVENSON. How do you expect to change the 10 milliwatt standard?

Mr. MURRAY. What was the question?

Senator STEVENSON. Let me ask the staff to ask the question.

Ms. NELSON. Can you speculate on what changes you will make in the present occupational exposure standard with respect to nonionizing radiation? Can you predict how the microwave standard might be changed?

Mr. MURRAY. I think primarily with what we know now, the radiofrequency band between 10 and 300 megahertz will be the part which is most likely to be changed, simply because it is written in the wrong terminology.

It should be in terms of the electric field strength, volts per meter, and the magnetic field strength, amps per meter, which the current American National Standards Institute (ANSI) standard adopted.

Going back to the fact there is very little biological-effects information available in the RF region, it is difficult to speculate whether the 10 milliwatt per square centimeter ($10mW/cm^2$) value is valid, or which way it will change, if it does change. The possibility of a recommended change, or the direction of change in the microwave region is also unknown at this time.

Ms. NELSON. When will the criteria document be published?

Dr. HARRIS. The RF/Microwave criteria document is scheduled to be published in fiscal year 1979. During that period, we will have an input in terms of some of the work which we have done. If additional information becomes available after the document is transmitted to OSHA, the document will be updated if necessary.

Senator STEVENSON. What are the major sources of worker exposure to ionizing radiation?

Mr. MURRAY. The three major sources are X-ray type devices, which includes industrial radiography and several other types of nondestructive testing; accelerators used for research and nondestructive testing, and radionuclides such as radium radon sources.

In terms of radionuclide sources, radium radon sources are primarily used for inspection purposes.

Senator STEVENSON. Does OSHA or NRC have responsibility for protecting workers in the uranium mining and milling fields from radiation?

Mr. HARRIS. That would be MESA, sir.

Senator STEVENSON. And the same would apply to coal mines?

Dr. HARRIS. I believe that would be true.

Senator STEVENSON. What do we know about exposure to radiation in coal mines?

Dr. HARRIS. At the present time, very little. We are doing some work on coal conversion, coal gasification and liquefaction. During the course of reviewing what is known about these processes, we have come up with the observation that a potential hazard could exist from the presence of radioactive material in some mines, or in the coal. Therefore, we are developing, as part of a program under EPA sponsorship, the control technology involved in reducing that potential radiation hazard to workers.

Senator STEVENSON. And the radiation comes from coal in gasification and liquefaction?

Dr. HARRIS. There is a possibility of the release of the radiation, or radioactive materials, in the gasification and liquefaction processes.

Senator STEVENSON. Not from the burning of gas and coal, but from the conversion of the coal to the oil and gas?

Dr. HARRIS. I cannot answer that. We do not know what would be residual in the gas or coal.

Senator STEVENSON. I thought you said earlier that it was released during the conversion process, not from the burning process.

Dr. HARRIS. That is right. We need to distinguish between the burning or combustion of coal, and conversion processes.

Senator STEVENSON. But it could come from the burning, too, if there is residual radioactivity in the oil that results from the burning of coal?

Dr. HARRIS. That is right.

Senator STEVENSON. But it does occur during the conversion?

Dr. HARRIS. That appears to be possible.

Senator STEVENSON. I was unaware of that. I had heard in the burning of the coal, radioactivity is emitted. Is there a worker-exposure problem in that event also?

Dr. HARRIS. This may very well be. This is what we are looking into.

Senator STEVENSON. That will be part of the study?

Dr. HARRIS. That is right.

Senator STEVENSON. Any——

Dr. HARRIS. As it applies to the workers, not as it applies to the general population.

Senator STEVENSON. Well, that ought to produce a lot of information and it might have broader implication.

When will this study be concluded?

Dr. HARRIS. I do not have that information right now.

Senator STEVENSON. Sometime after we have made the decision to convert to coal?

[The following information was subsequently received for the record:]

One gasification project was started in June 1976, another has just been initiated and is scheduled for completion during 1980. Preliminary work on the liquification project has begun. It is scheduled for completion during 1979.

Senator STEVENSON. What is the current personnel and funding level for NIOSH's efforts with respect to nonionizing radiation?

Dr. HARRIS. Currently, in the total radiation area, our total budget for fiscal year 1978 is approximately $360,000.

Senator STEVENSON. You mentioned a lack of a portable survey instrument for evaluating ultraviolet hazards. Have you been handicapped by the lack of such instruments for measuring other sources of radiation?

Dr. PARR. Yes; very much so.

Senator STEVENSON. And in OSHA?

Dr. PARR. OSHA probably has the same problem. One of the problems we have encountered is the lack of appropriate equipment to measure the near-field RF exposure levels. This has also limited the research which is necessary in this area.

After identifying the problem our first effort was to develop survey equipment under interagency agreement with the National Bureau of Standards. We have used this equipment in our surveys. We have also collaborated with OSHA, making measurements when requested. The one piece of equipment that is on the market now is the magnetic field detector. The electric field detector is still awaiting development.

Senator STEVENSON. The problem is not one of resources, it is just that the equipment has not been developed?

Dr. PARR. That is right. The equipment has not been developed. In the ultraviolet area, we have tried to develop a meter that would respond according to the standard recommended in the NIOSH criteria document. The exposure limits are wavelength-related. The meter we had developed was an excellent one. It worked very well, but could not be produced commercially.

We have since tried to develop and improve a second meter, which we are presently evaluating. This particular meter is a portable meter that could be placed in front of any ultraviolet source, and would read out the exposure level for all the different wavelengths with appropriate biological weighing.

All you would have to do would be to look at the table—developed as part of the meter—to determine the permissible exposure time.

Senator STEVENSON. Is industry responding to this need by developing other kinds of equipment to determine exposure?

Dr. HARRIS. Mr. Chairman, in many cases it is not a question of the lack of funds or the lack of desire. It is the lack of technology.

Senator STEVENSON. That is what we are getting at. That is what I am asking. Is it coming onstream. Is industry developing the technology?

Dr. Harris. With stimulation, it is; yes.

Senator Stevenson. With stimulation?

Dr. Harris. Yes.

Senator Stevenson. Where is the stimulation coming from?

Dr. Harris. Two sources.

No. 1, a requirement that there be such an instrument.

The other is the feeding of the development; feeding it by requiring or requesting that it be developed.

Senator Stevenson. Can you require them to develop?

Dr. Harris. Well, if this was a standard, you cannot have a standard unless—

Senator Stevenson. I understand that. I gather in some instances, as you have indicated, there are not true standards but rather guidelines.

Dr. Harris. That is right.

Senator Stevenson. In those I would assume there is not an overwhelming tendency to provide the equipment. From what you say, at least, a lot of the equipment has not been developed. The incentives apparently have not been there.

In those cases, to the extent they still exist, are the resources available with which to go out and buy the technology and develop it under contract?

Dr. Harris. In some cases, and not in others.

Senator Stevenson. There are not sufficient resources, in other words?

Dr. Harris. No; it is not a matter of not sufficient resources. Not sufficient technology.

Senator Stevenson. What I am referring to is the resources with which to contract for the development of that technology.

Dr. Harris. I cannot answer that. I do not know what resources are necessary.

Dr. Parr. I think you can see we have had an excellent relationship with the other Federal agencies in the development of our equipment.

Senator Stevenson. Well, gentlemen, you have been very patient. We are running late. I may need to follow up with some written questions.

Thank you, gentlemen.

Welding Safety.

SOME APPLICATIONS OF RF/MICROWAVE RADIATION IN INDUSTRY

Automotive

Heat-sealing: body interior trim panels, upholstery covers for seats and backs, convertible tops, drying of trim base panels, and embossing of heel pads to carpets.

Food Products

Finish-drying or "polishing" baked goods, melting chocolate prior to tempering, thawing frozen items, and inhibiting enzyme action.

Furniture-Woodworking Products

Plywood panel patching, lumber edge gluing, plywood or particleboard scarf gluing, laminated beams, veneer panel gluing, door lamination, ski lamination, and fiberboard fabrication.

Glass Fiber Products

Drying: glass fibers on forming tubes, roving packages, and coatings on continuously moving strands. Drying and curing sizing on machine packages.

Paper Products

Correcting moisture profile on continuously moving webs, heating coating on continuous webs, drying twisted twine packages, drying resin coatings, and gluing paper.

Plastic Heat-Sealing Products

Including: acetate box covers, advertising novelties, appliance covers, aprons, baby pants, beach balls, belts and suspenders, blister packages, book covers, capes, check book covers, charge cards, cushions, diaper bags, display boxes, electric blankets, equipment covers, food packages, fountain pens, garment bags, gas masks, goggles (industrial), hand bags, hat covers, index cards, lampshades, liquid containers, luggage, machine covers, mattress covers, milk cartons, oxygen tents, packages, pharmaceuticals, pillow cases, pillow packages, plastic gloves, pool liners, protective clothing, rain apparel, racquet and golf bags, refrigerator bags, shoes, shoe bags, shower curtains, slip covers, splatter mats, sponge backings, sport equipment, tobacco pouches, toys, travel cases, umbrellas, wallets, waterproof containers, and wire terminal covers.

Rubber Products

Preheating prior to molding and/or curing latex foams, and gelling and drying latex foams.

Textile and Fibers

Drying: rayon cake packages, wound packages, impregnated or coated yarns, slasher coatings, and continuous webs.

Other RF/Microwave Applications

Advertising—RF excited gas display signs.
Ceramics—dry ceramic items.
Chemical—activation of reactions.
Electronics—tube aging and testing.
Laser—RF-excited gas lasers.
Medical—diathermy and possible cancer therapy.
Scientific Equipment—low temperature ashing of samples.
Tobacco—dry blended tobacco and dry cigars.
Welding—RF stabilized welders.

[The following information was subsequently received for the record:]

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE,
NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH,
Cincinnati, Ohio, October 6, 1977.

Hon. WARREN G. MAGNUSON,
Chairman, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: This is in response to your letter of September 13, 1977, requesting additional information concerning NIOSH's program in radiation safety and health. Enclosed are five copies of the responses to the Committee's twelve questions and an additional ten attachments providing detailed information.

NIOSH appreciated the opportunity to testify at the radiation oversight hearing and is pleased to submit the additional documentation requested by the Committee.

Sincerely yours,

ELLIOTT S. HARRIS, Ph. D.,
Director, Division of Biomedical and Behavioral Science.

QUESTIONS FOR DR. ELLIOT HARRIS, NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH

Question 1. Please submit to the committee the following materials:

The FAA-sponsored study on baggage x-ray inspection equipment in which it was concluded that employee doses were well below the OSHA exposure standard.

Your prepared list of typical sources of exposure to workers from various forms of radiation.

A list of NIOSH publications concerning radiation.

Question 2. In your prepared comments the statement was made that "NIOSH has initiated a study to survey the current knowledge of radiation-induced carcinogenesis." How much of this information is available from other federal agencies? Does the NIOSH study represent a duplication of effort? Is not the BEIR report already being updated by others?

Question 3. During the Hearing, you stated that field studies have shown that 75% of the workers using radio frequency sealing and heating equipment were found to be exposed to radiation levels higher than the present occupational exposure guidelines. When were these measurements taken? How was this information transmitted to OSHA? Will efforts be undertaken to protect these workers pending completion of the study you mentioned?

Question 4. In response to a Committee question concerning FDA highlight achievements in radiation protection, the FDA states that with respect to airport baggage inspection units, it "began its investigation of the safety of these devices shortly after their introduction into U.S. airports in early 1973." The FDA reports it found excessive leakage and scatter radiation to operators and passengers being emitted by units and that it published an equipment performance standard applicable to airport baggage inspection units in 1974. Dr. Harris, in his pepared statement before the Committee, states that NIOSH evaluated "the potential radiation hazards to airport personnel working with baggage X-ray inspection units." In what manner did NIOSH coordinate its inspection of these baggage units with the FDA's BRH, particularly with respect to the FDA's equipment standard which was applicable to these units, and in light of the FDA's certification of the units for radiation safety?

You also stated that airport personnel working with baggage X-ray inspection units face a minimal radiation hazard. To what extent are these personnel routinely monitored for X-ray exposure? To what extent is equipment monitored for emission levels?

Question 5. How are you correlating your effort in setting a laser exposure standard with BRH's emission standards for lasers? When you state that the safety or engineering control procedures were found to be marginal or inadequate for 40% of lasers in use, what criteria were you using for making that judgment? Is there likely to be confusion on the part of users and manufacturers of lasers and laser products because of the difference between FDA and NIOSH on the matter of the number of classes into which lasers are divided?

Question 6. How serious is the problem of worker exposure to laser radiation at present? What should be done to minimize risk of overexposure in light of its increased use in the future?

Question 7. Please elaborate on the case of the young employees who developed bilateral cataracts after exposure to CRT and VDT. What is the statistical probability of cataract formation for employees of this age?

Question 8. On page 441 of the transcript you mentioned a retrospective epidemiological study which NIOSH may conduct to determine whether TACAN system repairmen exhibit an increased incidence of cancer, especially cancer of the pancreas. Assuming that your plans in this respect have now become more clearly defined, can you offer specifics about the study (i.e., expected duration, study design, budget) ? What is the probability of such cancer in men of the age of the two victims referred to above? Can you comment on the incidence of pancreatic cancer in the geographical area of Rhode Island? Is that entire area subject to more microwave exposure than is common in the rest of United States?

Question 9. You indicated the concern of NIOSH for the two TACAN system repairman who developed cancer of the pancreas. Paul Brodeur, in his December 1976 *New Yorker* article, claims that the Navy and NIOSH were less than responsive to allegations of a hazard associated with TACAN radar. Please submit your comments on this statement.

Question 10. Please cite the studies to which you alluded which "indicate that exposure of pregnant animals to RF radiation may harm the fetus."

Question 11. The Committee is interested in obtaining more information about the study NIOSH is seeking to sponsor on the radioactivity emitted during the burning of coal and during the conversion of coal via liquefaction and gasification processes. Do you have an idea as to when this study might take place and how soon conclusions might be made available to Congress?

Question 12. You state NIOSH established a radiation section in its physical agents effects branch in 1972. How many personnel does this section have, and what is its current funding level? In your opinion, are present funds adequate to carry out its assigned responsibilities? Do you think that it is necessary for NIOSH to have its own radiation section when ERDA, EPA, BRH, and others are currently involved in this area?

Answer 1. The report entitled "Documented Personnel Exposures from Airport Baggage Inspection Systems" is enclosed (Attachment A).[1] The study was sponsored by NIOSH at the request of the Air Transport Association (ATA) and coordinated with the FAA as mentioned in our testimony. Further discussion of the report can be found in the response to question four.

---

[1] Document is available from Superintendent of Documents GPO, Washington, D.C. 20402, HEW publication No. (NIOSH) 77-105.

The Physical Agents Chapter from the NIOSH publication entitled "Occupational Diseases" (in press) is enclosed (Attachment B). The chapter emphasizes the bioeffects of radiation but also includes information on typical applications/occupations in which various types of radiation sources are employed (see pp. 471–2, 475–7, 478–9, 486–8, and 495). NIOSH has found this information more useful than a directory or compendium of industrial radiation sources. Also enclosed is information on the estimated number of workers potentially exposed to ionizing, optical or RF/microwave radiation (Attachment C). The potentially exposed population has been estimated for each occupational category employed by the Bureau of Census and extrapolated to 1980.

Attachment D is the list of NIOSH publications concerning radiation.

Answer 2. The NIOSH radiation carcinogenesis literature review was initiated in fiscal year 1976 to investigate the carcinogenicity of ionizing and nonionizing radiation under the NIOSH cancer initiative program. Under this project, the world literature concerning radiation-induced cancer was reviewed and summarized in a state-of-the-art report on radiation carcinogenesis. Studies reported between 1971–76 were emphasized but earlier literature was referenced when necessary.

The report identifies the radiation types which have been shown to be carcinogenic in humans or animals and discusses possible mechanisms, threshold levels, dose-response relationship and synergistic effects. For other radiation types, studies relating to their potential carcinogenicity are discussed. Gaps in knowledge of radiation carcinogenesis are identified and recommendations made for future research needs. The report is currently in the final draft stage and will be published in three volumes early in fiscal year 1978.

In preparing the review, the contractor employed all information sources at his disposal including reports from Federal agencies and the listing of current Federal projects maintained by the Smithsonian Scientific Information Exchange. However, as an indication of the information available from other Federal agencies, less than ten percent of the references cited in the report was from Government agencies.

The wide scope of the review dictated that it be done extramurally. Extensive discussions were held with the personnel of BRH and the National Cancer Institute to avoid duplication of effort. Both agencies reviewed the contractor's draft final report. Copies of the review are enclosed (Attachments E and F).

The NIOSH report assesses the carcinogenic potential from both ionizing and nonionizing radiation. The BEIR I report of 1972 was accepted as conclusive up to its date of publication. The NIOSH volume on ionizing radiation carcinogenesis emphasized studies published from 1972–1976.

A second BEIR report (BEIR II) authored by the National Academy of Sciences (NAS) was recently released by EPA. The BEIR II report addresses only "the problem of evaluation of the total benefits derived from exposure to ionizing radiations for comparison with the total risks" and made no attempt to update the bioeffects literature.

NIOSH has learned that EPA has recently requested NAS to update the BEIR I report. Copies of the NIOSH review have been provided to NAS to be used as a reference base for their update, and to avoid duplicating effort.

Answer. The measurements on the industrial RF sources, upon which the 75 percent figure is based, were done in FY 75–77. The results were not formally transmitted to OSHA because its regulation cannot generally be applied to the RF (10–300 MHz) radiation region. The power density units (10 mW/cm^2) used in the OSHA regulation cannot be employed in making valid RF personnel exposure measurements. NIOSH's measurements were compared to the ANSI C95.1–1974 occupational exposure guides. However, the ANSI standard has an inadequate basis in bioeffects and consequently is of little value in determining the adequacy of worker protection.

Answer 4. The baggage x-ray study as mentioned in question one above was requested by the airlines through the Airline Transport Association (ATA) in 1974 because of concern expressed by airport personnel and the threatened close-down of baggage x-ray equipment in major U.S. airports. The investigation included ten airlines at five major U.S. airports and evaluated the potential radiation hazard to personnel operating the baggage x-ray systems. Whole body and wrist badges were issued to 72 security personnel for two-week intervals and then processed. The maximum exposure reading obtained was equivalent to five percent of the OSHA standard for whole body exposure and one-half percent for hand-arm (extremity) exposure.

BRH was informed of the objectives of the study but it was felt that due to the occupational nature of the problem and the fact that BRH standards do not address this issue no further coordination was necessary. However, BRH was sent the draft final report for review and comments relative to their baggage x-ray performance standard. The results of this study indicated that the BRH standard is effective not only in reducing the x-ray exposure of the general public but also in minimizing the occupational exposure to airport security personnel.

The conclusion that security personnel are exposed to a minimal radiation hazard with the use of the baggage x-ray units is based on the result of the hazard evaluation by NIOSH personnel and the BRH emission standard. NIOSH has no information on personnel monitoring and survey programs employed by the airlines or FAA.

Answer 5. NIOSH is not planning to develop a recommended standard for occupational exposure to laser radiation. Over the last several years, NIOSH has consulted with OSHA on the development of a proposed regulation which to date has not been promulgated. The latest draft of the proposed OSHA standard showed the same number of laser classes as the FDA/BRH standard. The proposed OSHA standard does divide Class III lasers into two groups. The BRH makes the same provision but has not formalized it in its classification scheme.

An occupational health survey of lasers was done in FY 68-69 to define specific problem areas related to the use of lasers. The survey consisted of two parts: (1) an interview with management to obtain information relating to the plant, health and medical programs, safety, etc., and (2) a walk-through survey of laser areas to observe environmental conditions. The latter part of the survey focused on the availability and use of procedural/engineering controls including warning devices, controlled access, beam enclosure, interlocks, reflective surfaces, safety eyewear, and protective clothing. Based on the professional judgment of the industrial hygienists performing the survey, each installation was evaluated as to the adequacy of the controls employed. A copy of the article describing the study in more detail is included for the Committee's information (Attachment G).

At OSHA's request, NIOHS published a compendium of all commercially available lasers in 1976. Each laser was classified according to the latest information available from OSHA on the parameters proposed in its draft regulation. Although the OSHA and BRH classes are essentially the same, a few lasers will undoubtedly be assigned different classes because of differences in measurement techniques specified for classification purposes. In general, the BRH measurement technique is more conservative and may result in the assignment of some lasers to a more hazardous classification. This is not surprising or unjustified since BRH is concerned with possible exposure to the general public and not solely occupational exposure. This should not cause any confusion among laser manufacturers or users as long as the difference and the rationale are understood.

Answer 6. Very few documented incidents of eye injury resulting from overexposure to laser radiation have been reported subsequent to the NIOSH occupational health survey of lasers. The laser performance standard promulgated by FDA/BRH should help to minimize the potential hazard by limiting the laser emission to which one could possibly be exposed. Promulgation of an occupational laser standard by OSHA would be useful in creating an awareness of potential laser hazards in the workplace and stimulating the development of occupational laser safety programs.

Answer 7. The two men who developed bilateral contracts worked for the New York Times. A complete radiation survey and medical evaluation was done by NIOSH and a report is currently in press. A copy of the draft report is enclosed and contains the details of the survey (Attachment H). Data from the National Eye Institute indicates that the probability of cataracts for males aged 25–44 years is approximately .00039 (3.9×10^{-4}) for the years 1970–73.

Answer 8. NIOSH has initiated a retrospective epidemiological study of TACAN and radar repairmen. The study is programmed for two years with a total budget of $215,000. The executive summary and the project protocol are enclosed (Attachment I).

According to statistics from the National Cancer Institute for the years 1950–1969, the probability of pancreatic cancer in white males aged 30–34 years is .0000046 or 4.6×10^{-6}. In regard to geographical incidence, no county in Rhode Island has a pancreatic cancer incidence which is statistically different from the U.S. rate. Several counties in southeastern Massachusetts and middle Connecticut do have statistically higher rates. However, NCI has concluded that there is no clearly discernible geographic pattern for the occurrence of pancreatic cancer.

NIOSH has no data on geographical patterns for microwave radiation exposure.

Answer 9. It is regrettable that Mr. Brodeur has implied that NIOSH has been less than responsive in investigating the occurrence of pancreatic cancer in two TACAN repairmen. NIOSH does not have right of entry to Federal facilities. At no time has NIOSH refused or even been reluctant to fully cooperate with the Navy in this matter. At the Navy's request, NIOSH has accompanied their personnel for meetings and surveys of TACAN repair facilities. NIOSH's personnel have virtualy been "on call" to assist the Navy in this investigation.

Answer 10. The list of studies documenting teratogenic effects in pregnant animals exposed to RF radiation is enclosed (Attachment J).

Answer 11. NIOSH currently has two programs addressing industrial hygiene problems associated with coal liquefaction and gasification processes. Both programs are being carried out by our Appalachian Laboratory for Occupational Safety and Health (ALOSH) in Morgantown, West Virginia. Each program requires the identification of radioactive materials released during the process and an evaluation of the potential hazard to the workers. The studies will be completed in fiscal year 1979. Because of the pressing need for guidance in this area, criteria documents are being prepared for coal gasification (scheduled completion fiscal year 1978) and liquefaction (fiscal year 1979) processes. New information from the ALOSH programs will be incorporated into updated criteria documents as soon as possible.

NIOSH has no information on releases of radioactivity to the environment from these processes or from the burning of coal.

Answer. The Radiation Section of NIOSH presently has a staff of five people and the total funding for fiscal year 1978 is approximately $360,000. This section has had considerable impact on the occupational safety and health field since its formation. The group members are well respected in their fields and function very efficiently as reflected in both the quality and quantity of accomplishments. At this time NIOSH feels that resources allocated for radiation research are sufficient to achieve our major goals with our present staff.

The occurrence of radiation sources has increased drastically over the past two decades in all phases of life. The industrial environment is no exception to this trend. In fact, occupational exposure to radiation sources may be accelerating at a faster rate in all types of industrial facilities outside of the nuclear industry than exposure of the general population. Thus, the consideration of radiation hazards has been integrated into the practice of industrial hygiene.

As stated, many Federal agencies presently have radiation research programs and NIOSH has keep abreast of the activities of these agencies. The obvious motive for such interactions is to avoid wasteful duplication of effort but, more important, to apply their research to NIOSH's needs whenever possible. By charter NIOSH must emphasize the protection of the Nation's workforce from all potential occupational hazards including radiation. The nature of the work environment is such that the worker is exposed to many stresses simultaneously, usually at higher levels than is the general public. Consequently, NIOSH's approach to solving the many problems found in the workplace may differ from that employed by other agencies in carrying out their missions.

For example, NIOSH is currently developing a criteria document for the roofing industry. In addition to the solar radiation ((UV, visible and IR) the roofer is exposed to several chemical substances, heat and noise. To provide adequate guidance to the industrial hygienist, all factors must be considered in evaluating and controlling hazardous situations including possible synergisms among the toxic agents. An interdisciplinary approach is mandatory in addressing such problems and expertise must be drawn from many fields to provide solutions.

Another point also deserves attention. With few exceptions other Federal agencies have concentrated their efforts and resources in ionizing radiation programs. NIOSH's Radiation Section has emphasized nonionizing radiation programs. This is obvious from the list of projects previously supplied to the Committee. RF and optical (ultraviolet, visible and infrared) are being given particular attention. Research is presently underway leading to the development of standards for RF and infrared radiation and the updating of ultraviolet radiation criteria document published in 1972.

Because of its overall mandate to occupational safety and health, NIOSH must actively maintain an overall programmatic approach to these issues. Since the Radiation Section provides necessary expertise to other projects and units with NIOSH in addition to its own projects, NIOSH feels that this Section should continue as an organizational entity.

ATTACHMENT B

PHYSICAL HAZARDS

The properties, biological effects, and health hazards associated with physical agents are discussed in this chapter. A physical agent can be defined as an entity without substance (i.e., with minimal matter), yet capable of affecting the biological mechanisms of an exposed worker. The hazards considered are those associated with exposure to the following agents, which will be grouped into three classes for discussion.

RADIATION: ionizing radiation and nonionizing radiation, including ultraviolet, visible, infrared, microwave, radio frequency, and laser.

ATMOSPHERIC VARIATIONS: heat, cold, air pressure.

OSCILLATORY VIBRATIONS: noise, vibration.

Some of these agents are encountered only in specific occupational situations while others may be present in a number of working environments.

RADIATION

Eugene Moss, William Murray, Wordie Parr, Ph.D.
and David Conover, Ph.D.

Radiation is energy which is emitted, transmitted, or absorbed in wave, or energetic particle, form. One can think of the wave as the disturbance that transfers energy progressively from one point to another point in a medium.

The electromagnetic (EM) waves consist of electric and magnetic forces. When these forces are disturbed, EM radiation results. The known EM radiations are grouped into a spectrum according to their frequency and/or wavelength (Table 7). The spectrum consists of a cotinuum of radiation ranging from below radio frequencies to above ionizing; it includes microwave, infrared, visible, and ultraviolet radiation. Although no range of radiation is sharply delineated from another and, in fact, the ranges often overlap, it is convenient to separate these ranges into the above groups because of the physical and biological effects associated with each radiation type.

The range of biological effects of exposure within the EM spectrum is extremely broad and diverse. This is further emphasized by noting the frequency bandwidth covered by the spectrum. Table 7 indicates the band width to encompass at least 10^{7} but, in fact, it extends to a factor of 10^{28} Hz. The amount of energy absorbed by the worker varies considerably over this range. The safety, health, evaluation, and control problems associated with such a range of magnitudes are great. No other area in human research has a similar wide range of the hazards that need to be considered, classified, and regulated.

Table 7. Characteristics and sources of electromagnetic radiation.

Type of radiation	Frequency range (Hz)*	Wave length range**(m)	Energy per photon range (eV)†	Typical industrial sources of exposures	Estimated number of exposed workers
A. IONIZING X-ray γ-ray B-ray γ-particle Proton Neutron	$>3.0\times10^{15}$	$<1.0\times10^{-7}$	$>1.2\times10^{1}$	Electronic tubes, radiography, nuclear power plants, radiation curing, medical uses, uranium mining, sterilization processes.	7×10^{3}
B. NONIONIZING Ultraviolet	7.5×10^{14} to 3.0×10^{15}	1.0×10^{-7} to 4.0×10^{-7}	3.1 to 1.2×10^{1}	Lamps, welding arcs, gas discharge tubes.	86×10^{3}
Visible	4.0×10^{14} to 7.5×10^{14}	4.0 to 7.6×10^{-7}	1.6 to 3.1	Lamps, welding arcs, hot bodies.	96×10^{3}
Infrared	3.0×10^{11} to 4.0×10^{14}	7.6×10^{-7} to 1.0×10^{-3}	1.2×10^{-3} to 1.6	Lamps, welding arcs, hot bodies.	26×10^{3}
Microwaves	3.0×10^{8} to 3.0×10^{11}	1.0×10^{-3} to 1.0	1.2×10^{-6} to 1.2×10^{-3}	Klystron, magnetron.	14×10^{3}
Radio Frequencies	$<3.0\times10^{8}$	>1.0	$<1.2\times10^{-6}$	Plastic sealers, furniture glue.	7×10^{3}

*Hz = Hertz, cycle per second. **m = meter. †eV = electron volts. Note: The given ranges are only approximations.

IONIZING RADIATION

Ionizing radiation has always been a part of man's natural environment, and since the discovery of X-rays and radioactivity, it has become a part of the industrial environment of many workers. The different types of ionizing radiation vary in their penetrative powers as well as in the number of ions they produce in traversing matter. The latter is important in that biological effects vary with ion density (the number of ions produced per unit length of track).

Ionizing radiations are produced naturally by the decay of radioactive elements or artificially by such devices as X-ray machines and high energy accelerators. A radioactive nucleus is one that spontaneously changes to a lower energy state, emitting particles and often gamma rays in the process. The particles commonly emitted are alpha particles and beta particles. High energy accelerators can produce all of the above particles plus protons, neutrons, and X-rays. The following sections describe some of the more commonly encountered types of ionizing radiation.

Alpha particles, which interact readily with matter to produce ions, usually have energies of from 4 to 8 million electron volts (Mev). They travel a few centimeters in air and up to 60 microns into tissue. The high energy and short path result in a dense tract of ionization along the path of the particles, which produces serious biologic damage in the tissues with which the particles interact. Alpha particles will not penetrate the stratum corneum of the skin and thus are not an external hazard; but if alpha-emitting elements are taken into the body by inhalation or ingestion, serious internal exposure problems may result.

Beta particles interact much less readily with matter than do alpha particles and will travel up to a few centimeters into tissue or many meters in air. Exposure to external sources of beta particles is potentially hazardous, but exposure internally is more hazardous.

Protons with energies of a few Mev are produced by high-energy accelerators and are quite effective in producing tissue ionization. The path length of a proton is somewhat longer than the path of an alpha particle of equivalent energy.

Gamma rays and X-rays are electromagnetic radiations with similar properties. X-rays, in general, have longer wave lengths, lower frequencies, and, therefore, lower energies than gamma rays. Gamma rays are produced by nuclear processes, while X-rays may result from the electronic structure of the atoms or from the slowing down of high-speed electrons. X-rays and gamma rays are primarily an external hazard and their biologic effects are better known than those of any of the other ionizing radiations. Examples of gamma emitters used in industry are cobalt-60, cesium-137, and iridium-192. X-rays may also be encountered during the manufacture and use of electronic tubes and electron microscopes.

Neutrons have about the same mass as protons, but react much differently since they are electrically neutral. These uncharged nuclear particles upon collision with matter may cause the release of all the above types of ionizing radiation. Neutrons can be produced up to several Mev by reactors, accelerators, or certain beryllium-enriched sources.

ROUTES OF ENTRY

The conditions presented by external radiation sources are entirely different from those presented by internal radiation sources which have been deposited in the body, with their attendant continuous irradiation of cells and tissue.

Entry of radiation sources into the body during occupational exposures is principally from breathing air containing particulate or gaseous radionuclides, although ingestion and skin absorption can be important.

Implantation under the skin may occur as the result of accidental skin puncture or laceration. Once inside the body, radionuclides are absorbed, metabolized, and distributed throughout the tissues and organs according to the chemical properties of the elements and compounds in which they exist. Their effects on organs or tissues depend on the type and energy of the radiation and residence time.

The effect from external radiation sources depends on the penetrating ability of the particular radiation. Thus, alpha radiation is of no concern externally, and beta is stopped in the outer tissues, the depth depending on energy. Very low energy X- or gamma radiation is attenuated quite rapidly.

HARMFUL EFFECTS

The early experience of radiation workers (including various nuclear accidents, exposure of radium dial-painters, casualties from atomic bomb explosions) and data from research projects provide clear evidence that high levels of ionizing radiation definitely create somatic damage and may induce genetic damage. The occupational somatic effects include radiodermatitis, epilation, acute radiation syndrome, cancer, leukemia, cataracts, sterility, and life span shortening. The genetic effects resulting from occupational exposures are to a great extent still unknown. Moreover, it is important to remember that a mutation produced by radiation is similar to one effected by a mutagenic chemical or to one occurring spontaneously.

In general, the sequence of events following radiation exposure may be classified into three major periods. The first period is the latent period, defined as the time lapse between the initial radiation event and the first detectable effect. Since the latent period can range from days to years, it is often divided into short-term (days or weeks) and long-term (months or years) effects. The second period, the period of demonstrable effects, occurs immediately after the latent period and is that time period when certain discrete biological effects can be observed. The final period is the recovery period.

The effects from occupational exposure to ionizing radiation are usually localized, leading to erythema or radiodermatitis. An acute radiation syndrome (ARS) episode occurs very rarely. An episode of this type involves whole body exposure exceeding 100 roentgens given in a very short time.

Initial symptoms of ARS are nausea, vomiting, diarrhea, weakness, and shock. Following a latent period of 2 to 14 days, symptoms of fever and malaise occur. During this same period of time, hemorrhagic lesions of the skin often appear, and by the third week, epilation occurs. Painful ulceration, both internal and external, may appear over the whole body and bloody diarrhea may occur. Death may result from severe bone marrow depression if the radiation exposure level is high. The patient is also susceptible to infection of many types.

Among the long term effects are an increased incidence of carcinoma, as noted in the radium dial painters and uranium miners; the embryological effects, as noted in pregnant working women; the cataractogenic effects, as seen in certain radiologists and nuclear physicists; and shortening of the life span.

Overexposure of a worker to either an external or internal source of radiation creates a medical emergency. In serious situations involving a release of radioactive material, the degree of contamination must be determined before the individual can be admitted to a hospital. A much more detailed discussion of the medical aspects of radiation accidents is available in the volume by Saenger (1963) listed in the bibliography that follows.

POTENTIAL OCCUPATIONAL EXPOSURES

With the widespread use of radioactive isotopes in industry and the increasing use of X-ray sources, ionizing radiation exposures may occur in a wide variety of occupations. The following examples show the diversity of occupations potentially exposed to ionizing radiation.

Aircraft workers
Atomic energy plant workers
Biologists
Cathode ray tube makers
Ceramic workers
Chemists
Dental Assistants
Dentists
Dermatologists
Drug makers
Drug sterilizers
Electron miscoscope makers
Electron microscopists
Electrostatic eliminator operators
Embalmers
Fire alarm makers
Food preservers
Food sterilizers
Gas mantle makers
High voltage television repairmen
High voltage vacuum tube makers
High voltage vacuum tube users

Industrial fluoroscope operators
Industrial radiographers
Inspectors using, and workers in
  proximity to, sealed gamma ray
  sources (cesium-137, cobalt-60,
  and iridium-192)
Klystron tube operators
Liquid level gage operators
Luminous dial painters
Machinists, fabricated metal product
Military personnel
Nurses
Oil well loggers
Ore assayers
Pathologists
Petroleum refinery workers
Physicians
Physicists
Pipeline oil flow testers
Pipeline weld radiographers
Plasma torch operators
Plastic technicians
Prospectors
Radar tube makers
Radiologists
Radium laboratory workers
Radium refinery workers
Research workers
Television tube makers
Thickness gage operators
Thorium-aluminum alloy workers
Thorium-magnesium alloy workers
Thorium ore producers
Tile glazers
Uranium dye workers
Uranium mill workers
Uranium miners
Veterinarians
X-ray aides
X-ray diffraction apparatus operators
X-ray technicians
X-ray tube makers

ULTRAVIOLET RADIATION

Ultraviolet (UV) radiation is an invisible radiant energy produced naturally by the sun and artificially by arcs operating at high temperatures. Artificial sources commonly found in industry are germicidal and black-light lamps, carbon arcs, welding and cutting torches, electric arc furnaces, and laboratory equipment.

Since the eyes and skin readily absorb UV radiation, they are particularly vulnerable to injury. The severity of radiation injury depends on factors which include exposure time, intensity of the radiation source, distance from the source, wavelength, sensitivity of the individual, and presence of sensitizing agents.

HARMFUL EFFECTS

Sunburn (erythema) is a common example of the effect of UV radiation on the skin. Repeated UV exposure of lightly pigmented individuals may result in actinic skin — a dry, brown, inelastic, wrinkled skin. There are telangiectases on the forehead, and neck movements produce lines on the nape in an angular pattern. Actinic skin is not harmful in itself, but it is a warning that conditions such as senile keratosis, squamous cell epithelioma, and basal cell epithelioma may develop.

Since UV radiation is not visible, the worker may not be aware of the danger at the time of exposure. Absorption of the radiation by the mucous membranes of the eye and eyelids can cause conjunctivitis (commonly known as "ground glass eyeball" or "welder's flash"). Lesions may also be formed on the cornea at high exposure levels (photokeratitis). Such injuries usually manifest themselves 6 to 12 hours after exposure. The injuries may be very painful and incapacitating, but impairment is usually temporary.

Photosensitizing agents have action spectra which are frequently in the ultraviolet range (Table 8). Some drugs and many plants, including figs, limes, parsnips, and pink-rot celery, carry photosensitizing chemicals believed to be furocoumarins and psoralens. Symptoms upon contact are those of an exaggerated sunburn with blisters frequently present. The most important industrial photosensitizer is coal tar which has an action spectrum in the visible range.

Ultraviolet light can also act in a nonspecific manner in the production of herpes simplex and chronic discoid lupus erythematosus.

PERSONAL PROTECTIVE METHODS

Protective measures are essential for workers exposed to high-intensity UV sources. Goggles, face shields, and masks provide protection for the eyes; protective clothing and barrier creams minimize skin exposure. Shiny metal surfaces reflect UV radiation and, when possible, should be removed from the work area. Reflections from lamp housings, walls, ceilings, and other surfaces should be reduced by coating these surfaces with a pigmented paint of low UV reflectance. Operations that produce high levels of UV should be placed behind enclosures to absorb the radiation and shield nearby workers from exposure.

POTENTIAL OCCUPATIONAL EXPOSURES

UV radiation exposure is generally present wherever occupations involve sunlamps, the outdoor sun, welding arcs, plasma torches, lasers, laboratory research, printing processes, drying and curing processes, nondestructive testing, environmental test chambers, medical devices and materials, and chemical processing and manufacturing. Occupations associated with potential UV radiation exposure include the following:

Agricultural workers
Bacteriologists
Bath attendants
Beauty salon workers
Brick masons
Cattlemen
Chemists
Construction workers
Dentists
Farmers
Fishermen
Food irradiators
Gardeners
Graphic illustrators
Greenskeepers
Horticultural workers
Laboratory workers
Lamp testers
Landscapers
Lifeguards
Lithographers
Lumberjacks
Maintenance workers
Meat curers
Metal casting inspectors
Microscopist
Military personnel
Movie projectionists
Nurses
Oilfield workers
Open pit-miners
Opticians
Optometrists
Outdoor maintenance workers
Paint and color testers
Paint curers
Physicians
Physicists
Physiological optics workers
Photo-bacteriologists
Phototherapy technicians
Pipeline workers

Table 8. Some examples of action spectra of normal and abnormal reactions in man.*

Condition	Wavelength Range (nm)	Maximum Reaction (nm)
Normal sunburn	290-320	297-307
Artificial light sources	250-320	250
Melanin pigmentation	290-320 320-480	290-310
Vitamin D production	290-310	290
Hyperbilirubinemia of prematurity	Blue visible spectrum	440-470
UV carcinogenesis	290-320	290-310
Solar urticaria	290-320 320-400 400-600	varying
Porphyria photosensitivity	380-600	400-410
Xeroderma pigmentosum	290-340	293-307
Polymorphic photodermatitis	290-320 320-400	290-320
Lupus erythematosus (LE) and discoid LE	290-320	
Solar (actinic) degeneration	290-400	?
Photoallergic reactions to halogenated salicylanilides and other related compounds	320-380	330-360
Phototoxic reactions to drugs	320-400 290-320	320-400
Psoralens (8-methoxy- and trimethylpsoralen)	320-380	330-360

Plasma torch operators
Plastic curers
Policemen (including crossing guards)
Postmen
Printers
Production workers in chemical
  processing
Railroad track workers
Road workers
Seamen
Ski instructors
Space simulator workers
Sportsmen
Surveyors
Textile inspectors
Tissue culture workers
Tobacco irradiators
Vitamin D synthesis workers
Welders
Welder foremen
Wood curers

VISIBLE RADIATION

Visible radiation, or light, from either the sun or artificial sources, is probably one of the more important occupational health considerations because of its major role in our daily life. Only within the last few years have investigators begun to discover various subtle physiological and biochemical responses to light.

Several human systems respond directly or indirectly to visible radiation. A direct effect has been defined as a chemical change in the composition of a tissue resulting from the absorption of light energy within the tissue. Because few direct effects of light have been documented, light is not considered a major occupational health hazard.

Indirect effects of light, however, can occur — not from absorption of light energy in tissues — but from the action of chemical signals liberated by cells in the body. Examples of this relationship of light to biological rhythms, include physical activity, sleep, food consumption, etc. Another well-known indirect effect is the inhibition of melatonin synthesis by the pineal gland which in turn affects maturation and activity of the sex gland. The various known classifications of abnormal biological reactions to light are shown in Table 9.

HARMFUL EFFECTS

One of the controversial issues associated with visible radiation is the effect of illumination on job performance. The concept exists that the levels of illumination and source luminance routinely encountered in interior working environments may constitute some type of an ocular health hazard. Studies on humans gazing at the sun and on rats and mice under common interior lighting intensities have produced evidence to indicate a hazard; these studies, however, have not been considered conclusive and the results have been disputed.

At the 1974 NIOSH symposium on illumination, several conclusions were agreed upon:

1) High levels of lighting can cause damage to the eye, i.e., retinal or macular degeneration
2) Poor lighting conditions can cause aesthenopia

3) With the possible exception of miner's nystagmus, such organic diseases as glaucoma, cataracts, and retinal degeneration do not result from exposure to low levels of illumination.

The consensus seemed to be that if there is sufficient illumination to perform a task reasonably well, then there is sufficient light to meet the safety criteria.

Although the etiology of asthenopia (eye strain) is debatable, it appears that repeated occurrences probably do not lead to any permanent eye damage. Workers over 40 years of age will probably encounter more symptoms of asthenopia (headache, tired eyes, irritation) since they require more light to perform a similar job than younger workers.

POTENTIAL OCCUPATIONAL EXPOSURES

Virtually all occupations offer exposure to the potential hazards of defective illumination. Some occupations, however, require unusually close, fine work and attention to detail for many hours a day. Some of these occupations are:

Draftsmen
Electronic equipment assemblers
Engravers
Jewelers
Quality control inspectors
Watchmakers

INFRARED RADIATION

All objects having temperatures above absolute zero emit infrared radiation (IR) as a function of temperature. In biological systems the major insult of IR occurs as a result of a rise in temperature of the absorbing tissue.

The physical factors associated with temperature rise are the wavelength, heat conduction parameters, exposure time, and total amount of energy delivered to the exposed tissue. Since IR photons are low in energy, they probably do not enter into photochemical reactions with biological systems. Molecular interaction with radiation in the IR regions are characterized by various vibrational-rotational transitions resulting in an increase in thermal energy of the molecule.

HARMFUL EFFECTS

Since the primary effect of IR on biological tissues is thermal, the skin provides its own warning mechanism by having a pain threshold below that of the burn threshold.

In the eye, however, there is no adequate warning mechanism to protect against lenticular damage. Cataracts may be produced by prolonged exposure to wavelengths at energy levels that do not normally burn the skin. The classic ocular effect observed after many years of IR exposure is a posterior cataract, sometimes called glassblower's or furnaceman's cataract. This type of cataract has a lengthy latent period (10 to 15 years) in individuals chronically exposed to IR which has made it difficult to determine threshold values.

The present etiology of IR-induced cataracts is thought to be directly correlated with the amount of energy initially absorbed by the iris and then transferred to the lens. The threat of cataract formation is primarily from wavelengths below 1400 nanometers. Longer wavelengths may produce corneal damage, the difference being due to the site of energy absorption.

The primary biological effect of IR on the retina and choroid is thermal in nature, with the amount of damage being proportionate to the length of exposure. If the radiation intensity is low enough, however, the normal retinal blood flow may be sufficient to dissipate any heat generated. Nevertheless, due to the focusing effect of the anterior ocular components, small amounts of IR radiation can produce a relatively intense point energy distribution on the retina resulting in a lesion. The effects of IR on the lid and cornea can be considered as ordinary cutaneous burns.

POTENTIAL OCCUPATIONAL EXPOSURES

A wide range of IR wavelengths representing large variations in temperature is encountered in many industries from direct (lamps) and indirect (heat) sources. Occupations potentially associated with infrared radiation exposures include the following:

Bakers
Blacksmiths
Braziers
Chemists
Cloth inspectors
Cooks
Dryers, lacquer
Electricians
Firemen, stationary
Foundry workers
Furnace workers
Gas mantle hardeners
Glass blowers
Glass furnace workers
Heat treaters
Iron workers
Kiln operators
Laser operators
Motion picture machine operators
Plasma torch operators
Skimmers, glass
Solderers
Steel mill workers
Stokers
Welders

MICROWAVE/RADIOFREQUENCY RADIATION

Various estimates have been made of the number of workers potentially exposed to microwave/radio frequency (RF) radiation sources in industry, including one estimate of approximately 21 million workers at risk (See Reference 110). Obviously, not every worker in every job is exposed to hazardous microwave/RF radiation levels, but an exposure of even 25 percent of the workers potentially at risk would still present a significant target population. Because of the size of this potentially exposed group at work, the continuing expansion of microwave use in industry, and the lack of widely known bioeffects data, a list of references is offered in citations to the material presented. Also the following

Table 9. Classification of abnormal reactions to light in man.*

Type	Light Alone	Light + Exogenous Agent	Light + Metabolite	Light + Abnormal Skin or Disease
Genetic	Ephelides (freckles)		Porphyrias: Erythropoietic porphyria Erythropoietic protoporphyria Variegate porphyria (mixed porphyria) Hereditary coproporphyria	Xeroderma pigmentosum Hartnup syndrome Oculocutaneous albinism Cockayne's syndrome Rothmund-Thomson syndrome Hailey-Hailey disease Vitiligo Darier-White disease Bloom's syndrome Phenylketonuria(?)
Chemical, phototoxic		Topical and oral drugs Phytophotodermatitis		
Chemical, photoallergic		Topical and oral drugs		
Chemical induction of disease		Lupus erythematosus from sulfonamides, hydralazine, reserpine, griseofulvin, oral contraceptives, etc.	Porphyria from hexachlorobenzene, estrogens, griseofulvin, stilbesterol, alcohol	
Nutritional				Kwashiorkor; Pellagra
Infectious				Lymphogranuloma venereum Herpes simplex

Table 9. Classification of abnormal reactions to light in man.* (Continued)

Type	Light Alone	Light + Exogenous Agent	Light + Metabolite	Light + Abnormal Skin or Disease
Degenerative and neoplastic	Chronic solar skin damage Solar keratoses Basal cell carcinoma Squamous cell carcinoma Malignant melanoma(?) Connective tissue degeneration (wrinkling) Telangiectasia			
Miscellaneous	Acute solar skin damage (sunburn) Hydroa aestivale and hydroa vacciniforme Disseminated superficial actinic porokeratosis	Phytophotodermatitis	Porphyria cutanea tarda	Lupus erythematosus (cutaneous and systemic) Solar urticaria Polymorphous light eruption Malignant carcinoid Pemphigus foliaceus Dermatomyositis

units of measurement are defined: μWcm^{-2} = microwatts per centimeter squared; MHz = 10^6 Hz; GH = 10^9 Hz; V•m^{-1} = volts per meter; and A•m^{-1} = amperes per meter.

HARMFUL EFFECTS

Effects from exposure to microwave/RF radiation due to heating have been well documented, but evidence for those occurring in the absence of a tissue temperature rise is incomplete and in dispute (1-3).

Frey (4) reported an acoustic response which he postulated to be a direct auditory nerve response to microwaves. The phenomenon occurred instantaneously in human subjects exposed to power densities as low as 100 μW•cm^{-2}. This specific effect was perceived as a buzz, ticking, or knocking, depending upon the pulse width and pulse repetition rate. The greatest sensitivity was observed in humans within the frequency range 300 MHz to 1200 MHz. The area directly over the temporal lobe of the brain was identified as the most sensitive area.

More recently Lebovitz (5) proposed that the cochlear hair cell structures within the vestibulo-cochlear complex of the human ear could directly respond to stimulation from pulse modulated microwave radiation. Guy (6) confirmed the reports of human auditory perception of pulse modulated microwave radiation and demonstrated a similar auditory response in cats which disappeared when the fluid was removed from the vestibulo-cochlear complex. Sommer and Von Gierke (7) confirmed the existence of this specific effect but stated that the effect was due to electromechanical transduction rather than direct stimulation of neural fibers or cortical neural tissue.

The possibility that microwave radiation could interact with the central nervous system (CNS) without detectable heating has been suggested by several investigators (8-18). Osipov (12) feels that some of the effects which have not been attributed to heating may in fact be due to microthermal heating. Microthermal heating is very localized and the temperature rise could not be detected by conventional temperature measurement techniques. Contrary to the subjective clinical complaints reported previously, recent studies [Baranski (8)] have used more objective measurements, better controls, improved statistics, a clearer description of the experimental design, and well documented experimental procedures.

In the Soviet and Eastern European literature (19-32), the following symptoms were reported as associated with 10/20-year exposure to microwave/RF radiation: headache, increased suspectibility to fatigue, diminished intellectual capabilities, dullness, partial loss of memory, decreased sexual ability, irritability, sleepiness and insomnia, and emotional instability. Objective disorders include sweating, hypotension, dyspnea, pains in the chest, sinus arrhythmias, bradycardia, and other cardiovascular problems. Electroencephalogram (EEG) recordings and the associated response times have been shown to be altered by microwave/RF exposure. Responses are characterized by initial excitation followed by inhibition. Also noted were threshold shifts generally in the direction of increasing thresholds for sensory perception, increases in the latent period of the condition-reflex reaction, and disruption of vegetative system regulatory and compensatory functions.

Other changes that have been observed are: in the histamine level in the blood (33-36), decreased cholinesterase levels in persons and animals exposed to microwave/RF radiation (37-43); alterations in the protein fractions, ions, histamine content, hormone and enzyme levels, and immunity factors (27,33-37,44-52); leukocytosis (monocytosis, lymphocytosis, and eosinophilia); recticulocytosis; and thrombocytopenia.

Of particular significance are studies of genetic and reproductive system effects because of the possible impact in large populations over long periods of time. One study suggested a possible correlation between paternal radar exposure and mongoloidism of the progeny (53). Several occupational studies have suggested possible disturbances in human reproductive system functions (27,33,54). Animal studies with low intensity exposures report reproductive system disturbances and cases of detrimental effects on the progeny (55-59).

Changes in menstrual patterns, retarded fetal development, congenital effects in newborn babies, decreased lactation in nursing mothers, and an increased incidence of miscarriages for women working with microwaves have been reported [Marha et al. (60,61]. As a result, Czechoslovakian employment practices (60) prohibit women of reproductive capacity from working with RF radiation sources. Teratogenic effects on the fetus of a mother treated with RF radiation at the beginning of pregnancy (62) and impaired embryogenesis in humans and animals, particularly when RF irradiation occurred during the initial stages of pregnancy (63) have been reported. Rubin (64) reported on a case of microwave exposure of the human female pelvis during early pregnancy and prior to conception. The patient was irradiated during the first 59 days of pregnancy and aborted on day 67. The author warned against treating pregnant women with microwave radiation unless a careful menstrual history is taken (64).

Microwave/RF teratogenic effects have been produced in mealworm beetle pupae (65, 66), chick embryos (67,68), rats (69), and mice (70). The teratogenic effects noted in rats (69) were produced following irradiation at the same frequency (27.12 MHz) where the majority of RF power sources operate. A single acute RF exposure for ten minutes at 27.12 MHz between the first and the 16th day of pregnancy was sufficient to produce teratogenic effects in rats (69). The head, palate, limbs, tail, and abdomen were malformed following RF irradiation.

Primigravid mice irradiated at 2450 MHz with an accompanying injection of cortisone on days 11, 12, 13, and 14 of gestation gave birth to greater numbers of stillborn and deformed fetuses (71). Microwave irradiation of white CF1 mice at 2450 MHz with a mean absorbed dose rate of 107 mW/gm for four minutes produced teratogenic effects on gestation days 3, 4, 8, 10, and 12 (72).

One of the more important bioeffects related to temperature rises induced by microwave radiation in biological media is cataract formation (73-81). Kramer et al. (82) concluded that a temperature of at least

41°C within the rabbit eye behind the lens is needed for cataractogenesis.

Weiter et al. (83) reported that the ascorbic acid content of rabbit lenses is a good index of microwave induced cataracts. The ascorbic acid content of rabbit lenses decreased with increasing microwave irradiation.

Behavioral effects observed after exposure to microwave RF radiation indicate that the modifications of normal behavior are related to the increased body thermal burden. Thomas et al. (84) observed that a rat's ability to perceive a constant time interval was degraded by irradiation for times sufficient to cause whole body heating. Hunt et al. (85) found that irradiation of rats at 2.45 GHz caused a decrease in their ability to swim a water alley and that errors of omission in performing visual discrimination tests increased immediately following microwave irradiation. Soviet investigators, however, have concluded that behavioral effects are not primary related to whole body heating (86).

A summary of available information on biologic effects and health hazards was presented in 1974 at an international symposium held in Warsaw, Poland (87).

Radio Frequencies Below 300 MHz

Previously, it was thought that there were no biological effects for frequencies below 300 MHz (0.3 GHz). Beginning in 1977, the United States Information Agency (USIA), and the United States Air Force (USAF) funded bioeffects research within the radiofrequency (RF) band which extends from 10 to 300 MHz in order to evaluate the accuracy of the 1977 standards for this frequency band. Both the ANSI C95.1 and the OSHA regulations (88) specify a frequency range from 10 MHz to 100 GHz.

Kall (89,90) studied the effects on rats exposed to RF (6 and 21 MHz) fields, similar to those found in the industrial environment. He noted that the gastrointestinal motor activity increased and cholinesterase activity decreased significantly. From the results of these studies on rats, Kall (90) recommended to the USIA that exposure standards should be modified to specify an electric field strength of 1500 $V \cdot m^{-1}$ and a magnetic field strength of 5 $A \cdot m^{-1}$ for the frequency range from 3 to 30 MHz.

The theoretical data of Lin (91) for a spherical phantom model simulating man has shown that the *magnetic field component* of the RF(1-20MHz) field may be the *most hazardous*. For RF fields close to typical RF power sources, the heating of the theoretical human phantom model due to the magnetic field component can be even larger. These conditions should be carefully considered when attempting to estimate the potential hazard from an RF radiation field.

Bawin (92,93) demonstrated EEG changes in cats and increases in calcium efflux in chicks following exposure to amplitude modulated 147 MHz fields. The amplitude modulation frequency (8-16 MHz) approached that of physiological bioelectric function rhythms. Further examples of alterations in circadian rhythms by RF exposure are effects on the cell division rate of corneal epithelium (94,95) and changes in rate of bone marrow cell mitoses (96).

Prince et al. (97) demonstrated that RF fields (10-27 MHz) can produce a marked increase in lymphocyte mitotic activity 71 hours post-exposure in monkeys. Lovely et al. (98) reported no in vitro lymphocyte mitotic activity 48 hours following RF exposure of monkeys.

Stavinoha et al (99) reported that near-field exposures of mice to 19 MHz caused definitive changes in lymphocytes and other white blood cells. The number of polymorphonuclear leukocytes was significantly higher and the number of lymphocytes was significantly lower in the irradiated group as compared with that of the control group. These alterations in white blood cells could not be duplicated in animals exposed in a hot air oven which elevated the colonic temperature the same amount as the RF field exposures. Czerski (95) showed alterations in the diurnal rhythm of peripheral white blood cells and granulocyte precursor mitoses in Guinea pig bone marrow. The results suggest a cumulative effect on the lymphatic system associated with decreased antibody production. This would imply that employees exposed to RF radiation might be more susceptible to infection and more susceptible to allergies encountered in the work environment.

The immunosuppressive and anti-lymphocytic actions of the adrenal glucocorticoids are well known. It is possible that immunologic effects caused by microwave RF fields are related to glucocorticoid levels. Guillet et al (100) reported the concentration of adrenal glucocorticoids in the blood increased following microwave irradiation.

Bollinger et al. (101) demonstrated that the uptake of H-3 Thymidine by lymphocytes isolated from mice exposed to RF fields ranged from 2.5 to 5 times that of control animals. Frazer (102) reported that the proportion of rat lymphocytes fell to 48.5% following RF irradiation. The total segmenters increased from 27.8 to 46.8%. It is not known whether these results indicate a direct effect on the cell population or an indirect thermal interaction followed by a rapid endocrine response. Froehlich (103) has shown that these effects could occur at the molecular level by either mechanism. Cody et al. (104) demonstrated alterations in the molecular spectra of biologically significant compounds, such as RNA, when exposed to RF radiation.

It is important to consider data which show that the distribution and magnitude of the absorbed power, *hence the expected biological effects*, varied greatly with exposure conditions. Bussey (104) found that the field intensity and distribution are markedly different in rats and primates. Guy et al. (106) measured field distributions in realistic models of man. The distribution of absorbed power in models of man was highly non-uniform with maximum power absorption (and associated localized temperature rises) occurring in the following locations: axilla, gonads, perineum, lateral thorax, ankles, sternum, forearms, tibia and fiibula, knees, neck, clavicle, shoulders and back. Persons industrially exposed to RF have complained of sensations of warming in many of the above mentioned locations.

Research (107-108) has indicated that the maximum amount of microwave/RF radiation is absorbed within the RF frequency range of approximately 25-26 MHz. Thus, consideration of the results of hyperthermia in the anatomical locations specified by Guy (106) should be of great interest.

For microwave/RF bioeffects dependent on power absorption, human RF exposures from approximately 25-26 MHz represent the greatest potential hazard. Industrial RF exposure measurements performed by NIOSH (109,110) show that the vast majority of industrial RF sources operate from 10-40 MHz and that more than 70% of the sources surveyed exceeded applicable personnel RF exposure standards.

POTENTIAL OCCUPATIONAL EXPOSURES

The following is a list of occupations with specific activities and/or products in which microwave/RF radiation is present and may be a potential hazard.

- Automotive workers
    - Drying of trim base panels
    - Embossing of heel pads to carpets
    - Heat-sealing body interior trim panels
    - Heat-sealing upholstery covers for seats and backs
    - Heat-sealing convertible tops
- Food products workers
    - Finish-drying of "polishing" baked goods
    - Inhibiting enzyme action
    - Melting chocolate prior to tempering
    - Thawing frozen baked goods
- Furniture and wood workers
    - Decking assembly
    - Door lamination
    - Fiberboard fabrication
    - Laminated beams
    - Lumber edge gluing
    - Plywood panel patching
    - Plywood or particleboard scarf gluing
    - Posts
    - Rafters
    - Ski lamination
    - Veneer panel gluing
- Glass fiber workers
    - Drying glass fibers on forming tubes
    - Drying roving packages
    - Drying and curing sizing on machine packages
    - Drying coatings on continuously moving strands
- Paper product workers
    - Correcting moisture profile on continuously moving webs
    - Drying twisted twine packages
    - Drying resin coatings

- Plastic heating sealing workers (cont.)
  - Gluing paper
  - Heating coating on continuous webs
- Plastic heat-sealing workers
  - Acetate box covers
  - Advertising novelties
  - Appliance covers
  - Aprons
  - Baby Pants
  - Beach Balls
  - Belts and suspenders
  - Blister packages
  - Book covers
  - Capes
  - Check book covers
  - Charge cards
  - Convertible tops
  - Cushions
  - Diaper bags
  - Display boxes
  - Electric blankets
  - Food packages
  - Fountain pens
  - Garment bags
  - Gas masks
  - Goggles (industrial)
  - Hand bags
  - Hat covers
  - Index cards
  - Lampshades
  - Liquid containers
  - Luggage
  - Machine covers
  - Mattress covers
  - Milk cartons
  - Oxygen tents
  - Packages
  - Pharmaceuticals
  - Pillow cases
  - Pillow packages
  - Plastic gloves
  - Pool liners
  - Protective clothing
  - Rain apparel
  - Racquet bags
  - Refrigerator bags
  - Shoes
  - Shoe bags
  - Shower curtains

  - Slip covers
  - Splatter mats
  - Sponge backings
  - Sport equipment
  - Tobacco pouches
  - Toys
  - Travel cases
  - Umbrellas
  - Wallets
  - Waterproof containers
  - Wire terminal covers
- RF/microwave application workers
  - Advertising — RF excited gas display signs
  - Ceramics — dry ceramic bodies
  - Chemical — chemical activation
  - Electronics — tube aging and testing
  - Laser — RF excited gas lasers
  - Medical-diathermy
  - Scientific equipment — low temperature ashing of samples
  - Tobacco — dry blended tobacco and dry cigars
  - Welding — RF stabilized welders
- Rubber products workers
  - Drying latex foams
  - Gelling latex foams
  - Preheating prior to molding
  - Preheating prior to curing latex foams
- Textile workers
  - Drying rayon cake packages
  - Drying wound packages
  - Drying impregnated or coated yarns
  - Drying slasher coatings
  - Drying continuous webs

LASER

The word laser is an acronym for "light amplification by stimulated emission of radiation." Lasers operate in the infrared and ultraviolet as well as visible regions. The name is descriptive of the physical principle involved in the production of the radiation. By stimulating or forcing atoms to emit photons, the resultant laser beam is coherent. This means that the photons in the beam are monochromatic and are in phase with each other. Since the laser beam is highly coherent it diverges slowly, maintains its divergency over a long distance, and has a high radiant exposure. As a result of these properties, laser light differs considerably from visible light.

At one time shortly after the development of the first working model in 1960, the laser was referred to as a solution looking for a problem. This situation has changed. By 1975 the development and marketing of new laser devices had resulted in the availability of almost 2500 models from 175 manufacturers and distributors. The most common lasers are shown in Table 10.

HARMFUL EFFECTS

The laser by virtue of its design is able to concentrate a large amount of energy in a small cross-sectional area. Consequently, individuals working with such devices encounter a potential hazard. The critical organs are the eye and skin and the resulting biological effects are similar to those produced by conventional optical radiation sources. Since energy must be absorbed to produce an effect, the degree of injury depends upon the wavelength of the laser and the capacity of the tissue to absorb energy of that particular wavelength.

The primary hazard from laser exposure is ocular damage. Overexposure of skin varies from a mild erythema to blisters and charring. Chronic or repeated exposures to laser radiation may have a long-term effect, but this is normally discounted.

Infrared radiation (700-1400 nm) has also been implicated as a cataractogenic agent. Overexposure to UV laser radiation can result in keratoconjunctivitis. Cataracts can be induced by UV lasers operating in the 300-400 nm range. Infrared lasers (1400 nm to 1 mm present a corneal hazard only.

PERSONAL PROTECTIVE METHODS

If the radiation levels are kept below those injurious to the eye, other tissues will not be harmed. The thresholds for skin and ocular damage are the same for both UV radiation and for IR (1400 nm – 1mm ranges. It is assumed that both organs are equally sensitive. The visible and near IR wavelengths (400-1400 nm) are readily transmitted through the ocular media to the retina. Not only is this radiation transmitted, it is focused by the lens onto the fovea centralis which concentrates the energy onto a very small spot.

Thus, in this spectral region, the eye (retina) is far more sensitive

Table 10. Common laser devices and applications.

Type	Wavelength(s)	Applications
Argon (Ar)	458-515 nm	alignment surveying instrumentation halography photocoagulation
Carbon dioxide (CO_2)	10.6 μm	material processing optical radar instrumentation surgery techniques
Dye	variable	instrumentation
Gallium arsenide (GaAs)	850-950 nm	instrumentation ranging intrusion detection communications
Helium cadmium (HeCd)	325, 442 nm	alignment surveying
Helium neon (HeNe)	632.8 nm	alignment surveying halography ranging intrusion detection communications
Neodymium glass (Nd glass) Neodymium YAG (Nd YAG)	106 μm	material processing instrumentation optical radar surgery
Ruby	694.3 nm	material processing holography photocoagulation ranging

than the skin by several orders of magnitude, and even a diffuse reflection from a high power laser can present an ocular hazard. An action spectrum has been recently developed to account for the variation in retinal sensitivity with wavelength for exposure times greater than 10 seconds. The minimum threshold dose for retinal lesions occurs at 440 nm and is thought to be due to a photochemical process rather than to a thermal mechanism as in wavelengths greater than 500 nm.

POTENTIAL OCCUPATIONAL EXPOSURES

Lasers are used in many diverse situations such as drilling holes in metals and baby bottle nipples, cutting diamonds, aligning wings on airplanes, repairing detached retinas, and taking three-dimensional pictures.

NIOSH ATTACHMENT C

ESTIMATED NUMBER OF U.S. WORKERS POTENTIALLY EXPOSED TO ELECTROMAGNETIC RADIATION

(By C. E. Moss, D. L. Conover, W. E. Murray, and A. Kohre*)

I. INTRODUCTION

Radiation is characterized as energy which is emitted, transmitted, or absorbed in wave or particulate form. Certain waves consist of electric and magnatic forces which when disturbed in some manner produce electro-magnetic (EM) radiation. The known EM radiations are grouped into a spectrum arranged by frequency and/or wavelength. The spectrum includes the radio frequency, microwave, infrared, visible, ultraviolet, gamma and x-ray regions. These regions of the spectrum are not sharply delineated from each other and, in fact, the regions often overlap. It is convenient to separate these regions as shown in Table 1 due to the nature of the physical and biological effects that are produced.

It is with the biological effects that the real need to comprehend the importance of the EM spectrum becomes apparent. Table 2 lists some of the reported biological hazards, ranked by a severity scale, that have been associated with the spectrum. One sees that the range of harmful biological insults produced by the EM radiations are very broad and diverse. While something is known about the various occupational hazards from EM exposures, very little information exists concerning (a) the number of workers by occupations exposed to EM radiation, and (b) the types of EM radiation sources that expose workers. Such information is essential if any meaningful occupational EM radiation safety program can be formulated. This paper categorizes, by occupations, those populations potentially exposed to EM radiation.

TABLE 1.—CHARACTERISTICS AND SOURCES OF ELECTROMAGNETIC-TYPE RADIATIONS

Type of radiation	Frequency range (hertz) [1]	Wave length range [1]	Energy per photon range	Typical industrial sources of exposures
Ionizing	$3^{21}\times10^{21}$ to 3×10^{16}	<10 nm	>124 eV	Medical uses, nuclear powerplants, accelerators.
Ultraviolet	3×10^{16} to 7.9×10^{14}	10 nm to 380 mm	124 eV to 3.3 eV	Lamps, welding arcs, gas discharge tubes.
Visible	7.5×10^{14} to 4×10^{14}	380 nm to 750 nm	3.3 eV to 1.6 eV	Lamps, welding arcs, hot bodies.
Infrared	4×10^{14} to 3×10^{11}	750 nm to 1 mm	1.6 eV to 1.2 meV	Lamps, welding.
Microwaves	3×10^{11} to 3×10^{8}	1 mm to 1 m	1.2 meV to 1.2 meV	Klystron, magnetron.
Radio frequencies	3×10^{8} to 3×10^{5}	1 m to 1 km	1.2 meV to 1.2 meV	Transistors, tuned circuits.

[1] The given ranges are only approximations as no exact end-point can be defined.

TABLE 2.—KNOWN HUMAN BIOLOGICAL EFFECTS FROM ELECTROMAGNETIC RADIATION EXPOSURE DEGREE OF SEVERITY

Radiofrequency and microwave radiation	Optical radiation	Ionizing radiation
Death, genetic effects, teratogenic effects, behavioral effects, cataract, acoustic response, nervous system disorders, headache, blood level changes, loss of memory, dullness, sleepiness, sinus arrthymias.	Skin cancer, squamous and basal cell epithelioma, herpes simplex lesions, cataract, retinal damage, genetic alteration, erythema, keratoconjunctivitis, heat stress, cutaneous burns, variance in biological rhythms, asthenopia.	Death, cancer, leukemia, sterility, cataract, radiodermatitis, ulcerations, erythema (burns), genetic alteration, blood cell changes, malaise, fever, nausea, weakness, shock, diarrhea, life span shortening, anorexia.

II. SOURCE OF INFORMATION

The background for this work was initiated in a previous NIOSH publication that developed a partial list of occupations exposed to certain agents, including physical agents. However, the publication did not estimate the total number of workers at risk in any EM region. Other sources of information used for this study were NIOSH reports and studies, open literature articles, U.S. Census Bureau population estimates, world almanacs, personal contacts, and certain trade organizations. In addition, details from various measurments made by the NIOSH Physical Agents Effects Branch were incorporated into this report.

III. METHODOLOGY

Using the United States Census Bureau major occupational categories charts were developed listing the various types of workers by occupational catagories. A sample chart used in the work is shown in Table 3. Extrapolations were made from 1960 and 1970 civilian workforce figures to a 1980 estimated workforce value. The results of the overall determination for these categories are shown in Table 4. Next, a judgement was made for every occupational classification within the categories to determine which EM region exposure was possible. In this decision process, the following assumptions were made:

Short

TABLE 4.—ESTIMATED NUMBER OF WORKERS IN CIVILIAN LABOR FORCE BY 1980

[In millions]

Major occupational categories	Number of male workers	Number of female workers	Number of total workers	Percentage of category to total workers
Professional, technical and kindred workers	8.980	5.930	14.920	15.25
Farmers and farm managers	1.050	.050	1.100	1.12
Managers, officials and proprietors	6.797	1.523	8.320	8.51
Clerical and kindred workers	4.293	14.217	18.510	18.92
Sales workers	3.780	2.835	6.615	6.76
Crafthmen, foremen and kindred workers	12.176	.809	12.985	13.27
Operative and kindred workers	9.749	6.111	15.860	16.21
Private household workers	.030	.970	1.000	1.02
Service workers	4.770	5.930	10.700	10.94
Farm laborers and foremen	.745	.155	.900	.92
Laborers	3.420	0	3.420	3.50
Transport equipment operators	3.292	.198	3.490	3.57
Total	59.082	38.738	97.820	100.00

(*a*) Unless otherwise noted, if one worker within a particular occupational classification is exposed to a certain EM region, then all workers will be considered as being potentially exposed. This assumption will result in total estimates being higher than actual.

(*b*) The EM region chosen will best reflect the major daily insult to the particular classification in question. However, if the workers are judged to receive potential exposure from two or more EM regions, then two or more will be shown.

(*c*) Due to the difficulty in separating exposures to the optical radiation region, source descriptions are used rather than radiation region. This action is necessary since ultraviolet, infrared, and visible radiation are produced simultaneously by many sources. Furthermore, occupational exposure to the sun made it useful to classify workers' exposure by source type. Table 5 indicates the difference in exposures from natural and artificial sources. Lamps includes all types of incandescent, electric-gas discharge, and fluorescent sources while the other nomenclature refers to lasers, and various type of arcs.

(*d*) The relative risk or degree of hazard to any agent is not considered in developing the number of potentially exposed workers.

TABLE 6.—NUMBER OF WORKERS IN MAJOR OCCUPATIONAL CATEGORIES POTENTIALLY EXPOSED TO VARIOUS REGIONS OF THE ELECTROMAGNETIC RADIATION SPECTRUM

		Electromagnetic radiation region					
		Optical		Microwave and RF		Ionizing	
Major occupational categories	Number of workers in categories ($\times 10^6$)	Number exposed Percent ($\times 10^6$)	Percent	Number exposed ($\times 10^6$)*	Percent	Number exposed ($\times 10^6$)	Percent
Professional	14.920	16.340	14.7	4.180	19.8	1.791	25.9
Farmers	1.100	1.100	1.0	0	0	0	0
Managers	8.320	8.740	7.9	1.070	5.1	.290	4.2
Clerical	18.510	18.710	16.8	0	0	.300	4.3
Sales	6.615	6.945	6.2	0	0	.052	.8
Craftsman	12.985	14.625	13.1	5.615	26.8	1.450	21.0
Operative	15.860	18.705	16.8	4.725	22.4	2.391	34.6
Private HH	1.000	2.000	1.8	.200	.9	0	0
Service	10.700	15.066	13.5	2.410	11.4	.175	2.5
Farm laborers	9.000	.900	.8	0	0	0	0
Laborers	3.420	3.942	3.5	.172	.8	.262	3.8
Transport	3.490	4.200	3.8	2.690	12.8	.200	2.9
Total	97.820	111.273	100.0	21.062	100.0	6.911	100.0

*Number of people exposed may exceed the actual number of workers due to exposures of multiple agents.

Using the above assumptions and sources of information as guidelines, it was possible to proceed with the stratification of potentially exposed workers into EM regions. In many instances there was no information to guide the division process and hence "best guess" techniques were employed. For example, trying to estimate the percentage of all teachers who would be expoesed to the ionizing radiation region on a regular basis. The results of stratifying every occupational classification and totaling the results of the 12 major categories are shown in Table 6.

Finally, in the optical radiation region, the top two potentially exposed categories are the operative and the clerical workers. Each of these categories represent about 17% of the total workforce. Furthermore, it appears that almost 20% of the total workforce in this region will receive their main optical exposure from the sun, while almost all of the workforce will be exposed to lamps of some type.

IV. RESULTS

Using Table 6 it is clear that in the ionizing radiation region the operative and kindred workers' occupational category is the most potentially exposed group, followed by the professional, technical and kindred workers category. The difference between these two job categories is greater than that which exists for the top two categories in the other two regions. Over ⅓ of all the people exposed in this region are members of the operative category.

The ranking of the categories in the microwave and RF region are much closer together with the craftsman category having more potential exposures than the operative category. Almost ½ of all people exposed to microwave and RF region are members of these two categories. There are three times as many people exposed to the microwave and RF region as there are to be the ionizing region.

TABLE 5.—BREAKDOWN OF OPTICAL RADIATION BY TYPE OF SOURCE

Major occupational category	Number of workers in category ($\times 10^6$)	Number of workers exposed to ($\times 10^6$)		
		Natural source (Sun)	Artificial sources	
			Lamps	Others
Professional	14.920	1.740	14.920	0.680
Farmers	1.100	1.100		
Managers	8.320	.160	8.320	.260
Clerical	18.510	.200	18.510	
Sales	6.615	.570	6.375	
Craftsman	12.985	3.095	7.030	4.500
Operators	15.860	.665	15.835	2.205
Private HH	1.000	1.000	1.000	
Service	10.700	3.581	10.185	1.300
Farm laborers	.900	.900		
Laborers	3.420	2.459	1.453	.030
Transport	3.490	2 905	1.295	
Total	97.820	17.375	84.923	8.975

As of this date, this work has pointed out the following general conclusions:

(*a*) In many cases, workers are potentially exposed to more than just one region of the EM spectrum.

(*b*) The number of workers potentially exposed to optical, microwave/RF and ionizing regions of the EM spectrum in 1980 are estimated at 111, 21, and 7 million, respectively.

(*c*) The operative and kindred workers' category is the group which receives the greatest contribution from all of the regions. Table 7 indicates a few of the occupations making up this category. Since approximately 40 percent of the workers in this category are female, then one would expect to find many women potentially exposed to certain EM regions.

In summary this paper has made an initial attempt to estimate the number of workers potentially exposed to various regions of the EM spectrum by 1980. Obviously the absolute value of any number presented in this paper is subject to much question due to the many sources of error inherent within the stated assumptions. Nevertheless it is hoped that such an atempt, crude as it may appear, will create further thought and ultimately, better estimates. Performing a limited survey of those occupations comprising the operative and kindred workers' category would be one suggestion that might help to partially confirm estimates given in this paper. The authors invite comments and/or criticism on these estimates. In later presentations, estimations will be made on the number and type of workers actually exposed to various regions of the EM spectrum. In addition, occupational categories will be examined for typical EM sources used as well as typical exposure values. Such information could then be used to assess relative risk factors.

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE,
NATIONAL INSTITUTES OF HEALTH,
NATIONAL CANCER INSTITUTE,
Bethesda, Md., August 16, 1977.

Dr. WILLIAM E. MURRAY,
Chief, Radiation Section, PAEB, National Institute for Occupational Safety and Health, PHS, DHEW, Robert A. Taft Laboratories, Cincinnati, Ohio

DEAR DR. MURRAY: I am sending copies to you of the very brief comments made by Dr. Upton and by our ICRDB Program staff relating to the Franklin Institute review of the literature on radiation carcinogenesis. I have also sent the document today to Dr. Francis Mahoney who is in charge of the extramural radiation program of NCI. He will return the document with his comments directly to Mr. Dwyer.

In general, it is my feeling that this is a valuable report and reference source. We will certainly make it known through our information program.

I appreciate your interest in our program and hope that we may find ways of working together in the future.

Sincerely,

GREGORY T. O'CONOR, M.D.,
Associate Director for
International Affairs,
National Cancer Institute.

Enclosures.

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE,
PUBLIC HEALTH SERVICE,
NATIONAL INSTITUTES OF HEALTH,
NATIONAL CANCER INSTITUTE.

Memorandum to: Associate Director for International Affairs, NCI
From: Director, NCI.
Date: August 10, 1977.
Subject: Franklin Institute Report on Ionizing and Non-Ionizing Radiation.

Thank you for letting me review the attached report entitled "A Current Literature Report on the Carcinogenic Properties of Ionizing and Non-Ionizing Radiation," prepared by the Franklin Institute Research Laboratories Science Information Services.

I regret that I have had no time to go over the report critically and in depth. On the whole, however, I consider it to be relatively good, comprehensive, and up-to-date.

Some of the flaws that came to my attention include the following:

Table 20 (page I–34): This ranking of relative sensitivities is now outdated in that the breast should be transposed to the high sensitivity category (see Upton et al., "Final Reports of National Cancer Institute Ad Hoc Working Groups on Mammography Screening for Breast Cancer and a Summary Report of Their Joint Findings and Recommendations").

Tables 36 and 37 (pages I–94, 95): The NCRP report quoted as a source has not been published and may not be published. Hence, the basis for these inferences and recommendations is not accessible to the reader for adequate documentation.

ARTHUR C. UPTON, M.D.

Enclosure.

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE,
PUBLIC HEALTH SERVICE,
NATIONAL INSTITUTES OF HEALTH,
NATIONAL CANCER INSTITUTE.

Memorandum to: Dr. Gregory T. O'Conor, Associate Director for International Affairs, NCI.
From: Dr. John H. Schneider, ICRDB Director, OIA, NCI.
Date: August 2, 1977.
Subject: Review of the First Draft of the Document Prepared by Franklin Institute called "A Current Literature Report on the Carcinogenic Properties of Ionizing and Non-Ionizing Radiation."

Dianne and I have both reviewed this document briefly. We find the following:

(1) It appears to be quite comprehensive and detailed.

(2) The style is good and quite readable. The writer(s) is clearly an experienced professional who knows the subject quite well and knows how to express the subject matter well.

(3) The level of obvious errors is very low. Only one misspelling was found in a quick scan of many pages.

(4) The tables in section I were particularly well organized and well presented.

Minor questions:

(1) Would it be possible to increase the number of 1976/1977 references to make it appear more current? Were all available documents during the past year and a half included if possbile?

(2) The coverage of cancer causation by radioisotopes may possibly be limited. I would have guessed that there was enough data on this to give several tables listing experiments where radioisotopes were administered to animals (both acute and chronic), but I saw relatively little on this. Perhaps it should be in a separate section.

(3) The section on exposure to microwave radiation might include information about the exposure in terms of mW/sq. cm. as a function of distance and time of exposure to common microwave sources (such as microwave ovens, radiofrequency transmitters, etc.) I assume this data is available, and it may have been included, but I didn't see it in a quick scan.

(4) I am surprised that there is only one reference to Carpenter in the microwave radiation section, since I know he is considered one of the key specialists in this area.

(5) Would a brief alphabetical index be of use?

In addition, both Dianne and I would like to know:

(1) More about the number and qualifications of the people who participated in the preparation of this document. We both feel this should be reflected to some extent in a preface so that users would know how much credence to give to the document.

(2) How long it took to prepare the document and the cost of preparation.

(3) Who the specific users are expected to be and what specific uses NIOSH expects to be made of the document? There are probably several reviews or books covering each area included in this report and written by a widely recognized specialist in each specific area every year. Perhaps the document was intended to provide background for administrators or as a general reference document. In this case, the brief alphabetical index might be particularly useful.

MR. MICHAEL J. DWYER,
Group Manager, Biomedical Projects, The Franklin Institute Research Laboratories, The Benjamin Franklin Parkway, Philadelphia, Pa.

DEAR MR. DWYER: Thank you for the opportunity to review the first draft of *A Current Literature Report on the Carcinogenic Properties of Ionizing and Non-Ionizing Radiation.*

The draft has been reviewed by several members of the Division of Biological Effects of our Bureau whose comments, which are attached, have been grouped by type of radiation, in accordance with the presentation of the material.

The document is being returned as you requested.

Sincerely yours,

JOHN C. VILLFORTH,
Director, Bureau of Radiological Health.

Enclosures.

IONIZING RADIATION CHAPTER

The writing is very clear and the organization well suited to the material. While the coverage is broad, this section is essentially a review of other reviews and, therefore, subject to selection bias both by the original reviewer and the authors of the report.

Nearly two-thirds of the Tables and Figures came from two sources, with only the order of presentation changed. Figures 5–9 and Tables 25–35 are from the BEIR report. Figures 2, 3, 13–23, and Tables 5, 7–9, 16, 19, and 20 are from Becker, in Cancer, a comprehensive treatise, which included reviews by Upton, Kellerer and Rossi, and Storer. The BEIR report attempts to fit everything to the "linear non-threshold" hypothesis. The Franklin Institute terms this approach as "administrative". The latter review provides much of the same material used by the NCRP Scientific Committee 40 in presenting the "linear-quadratic" model, with its inherent "dose effectiveness" factors. The Franklin Institute Review terms this as the "scientific" approach. The Franklin Institute definitely sides with the latter approach and doesn't differ very much in presentation or conclusions from the NCRP Scientific Committee 40 draft document. It should be noted that the NCRP document is still a draft document by one committee of the organization and has not been adopted by NCRP as a whole. The "dose effectiveness factors" concept has not yet been accepted by NCRP as policy, and indeed is still undergoing refinement as witnessed by Dr. Victor Bond's recent presentation at the Radiation Research Society Meetings.

Coverage of the epidemiologic material is incomplete and not up-to-date, and interpretations do not reflect differing viewpoints on important controversial subjects or needs for future study. Because of the method of review, with only occasional reference to original sources, findings are repeatedly attributed to reviewers rather than investigators, which makes for rather strange reading for those acquainted with the field.

A number of the cited references have been followed by later publications which are more complete or definitive.

It will be helpful to note in a Foreword the purpose of the report, method of assembling information and intended audience.

ULTRAVIOLET, VISIBLE, AND INFRARED RADIATION CHAPTERS

Comments are limited to substantive issues and impressions; the review is not therefore detailed and technical. Overall comments are summarized as follows:

(*a*) The reviewer(s) have performed an impressively thorough job of reviewing published literature, and have performed selective follow-up on some points. There is little evidence, however, that independent judgment has been exercised about validity of observation, either in the context of related research or of principles of biological organization and function. As examples of the independent judgment, we cite the following:

(1) The discussion of augmentation of mutations by caffeine and light leads to a distinction between mutagenesis and lethality which, in the current context, presents a conflict with the statement of augented mutagenesis.

(2) The discussion of photo-reactivation in human cells presents the worker's interpretation of observed phenomena as the phenomena on which the measurements were made. This distinction is considered critical by workers in the field, inasmuch as the evidence, however indirect, is scanty for photo-reactivation in human cells, and largely unsupported by independent tests.

(3) The presentation of the Forbes data on ultraviolet A and ultraviolet B interactions, and the discussion of the Bradley data on visible light effects, fail to present caveats about spectral distributions known from the sources used.

(4) The Hart and Setlow observations of tumor induction by ultraviolet are in question, by virtue of the fact that the tumors induced are well-known and associated explicitly with a microorganism contamination that was uncontrolled in the study.

(5) The information that 8-methoxypsoralen may protect against neoplasia is probably a premature judgment, on the basis of lag times for cancer induction. In addition, the reference associated with this information (Carter et al., 1976) should be re-checked—the data in the referenced paper deals with chromosome structural aberration induction. As evidence for or against radio-protective effects, the use of aberrations represents a large stretch of conditional caveats and interpretations.

(*b*) The apparent correlation between sunlight and melanoma should be included early in the section, "Types of malignancies observed in man." While data on melanoma induction with light are not as extensively reported as the data on carcinomas, they appear to have been independently confirmed.

(*c*) The considerable discussion on mechanisms of UV injury leading to carcinogenesis leads to the conclusion that the unrepaired damage is potentially dangerous. Further types of injury, now well-studied in Experimental Studies Branch (DBE, BRH) as well as other laboratories, are not mentioned. These include enhancement of cell transformation by viruses from lytic to oncogenic phases, activation of latent tumor viruses, and error-prone synthesis of DNA, or misrepair of UV damage, in which functional capacity of damaged DNA is restored via introduction of mutated sequences of bases in the DNA. It is now known that the last type of damage accounts for the majority of mutation induced in bacteria by UV radiation exposure.

(*d*) The section on co-carcinogenesis reflects the complexity, confusion, and incompleteness of the research record. It lacks some overall summation for such a perspective of current knowledge. There is a special case of what can be considered co-carcinogenesis—photosensitive people. At preesnt no mention is made of such individuals in the sense of their cancer experience and radiation protection. There exists a discussion of xeroderma pigmentosa from the standpoint of repair of radiation damage. We believe that the variability of photosensitivity, on bases other than race and pigmentation of the skin, should be included.

MICROWAVE AND RADIOFREQUENCY RADIATION CHAPTER

Comments are limited to substantive issues and impressions, so that the review is not detailed and technical. Our comments are summarized as follows:

(*a*) The discussion on cumulative effects should be reconsidered to include (1) an operational distinction between synergistic and cumulative effects, clearly stated, (2) explicit awareness that the Carpenter cataract experiments reported by Carpenter et al., 1974, as referenced, are considered by Carpenter to constitute evidence of cumulative effects, as well as by Shore, (3) additional studies on possible cumulative effects, such as Baillie at the Richmond Symposium, and (4) additional studies on possible synergistic actions, such as Lappenbusch et al., Radiation Research, 1973 and research on microwave and x-rays by Rugh and coworkers.

(*b*) No mention was found of the Prausnitz and Susskind study (IRE Transaction on Bio-medical Electronics, 1962) in which increased incidence of leucosis and leukemia in irradiated mice. While the published report can be considered incomplete with respect to a number of important details, such additional information may be available in reports to the Federal sponsor of the research.

(*c*) Because of the subject area of the review, it may be appropriate to recognize the long-term failure to follow-up on the Prausnitz-Susskind observations and therefore to list current studies in progress which are designed to examine the question of microwave and radiofrequency carcinogenesis. We know anecdotally of instances in which foci of unusual cancer are found in occupational settings; some of these are under study.

ATTACHMENT G

A Preliminary Study of National Health Hazards from Lasers

MARSHALL LaNIER,* VERNON E. ROSE, and CHARLES H. POWELL, Ph.D.†

Bureau of Occupational Safety and Health, Environmental Control Administration, Consumer Protection and Environmental Health Service, Department of Health, Education and Welfare, 1014 Broadway, Cincinnati, Ohio 45202

The techniques of industrial hygiene and epidemiology have now been combined in an effective survey procedure that permits the assessment of potential occupational health hazards associated with laser operations. Included in this assessment are such factors as the physical characteristics of the laser and laser area, the operating procedures and controls, and health services and programs available to the laser operator. Results are based on a statistical sample of the lasers in the United States and are representative of industrial, research, communication, and educational groups who are known to use lasing devices.

Introduction

AS NEW APPLICATIONS are developed, the use of laser systems in research laboratories, educational institutions, and electronic and other industries is rapidly expanding, with a concurrent increase in the number of workers exposed to the potential health hazards associated both directly and indirectly with the use of these devices. As with many research and industrial processes, the development of new sources of energy and the expanding use of these devices may be accompanied by neglect or lack of knowledge on the part of the user of the potential hazards associated with such items. Also, the basic principles associated with safe use and health protection practices involved in the operation may be neglected. This lack of understanding and knowledge of the potential health hazards is intensified when basic information relative to techniques for the evaluation and control of these hazards has not been developed. The significance of potential biologic damage from both acute and chronic exposure of workers to coherent energy from lasers, the adequacy of present methods of protection, and the magnitude of the health problem must be explored before any adequate national health program can be logically developed regarding the use of lasers. In an attempt to define, at least in part, the specific occupational health problems associated with the use of lasers, and to assess the technical assistance, research, and training required to reduce these potential health hazards, a nationwide epidemiologic study was made of laser operations. This paper reviews the results of that study.

Experimental Design

The laser survey was designed to obtain information of value to state and federal governments, the laser industry, and industrial and health organizations in evaluating the effectiveness of laser safety and health activities and in planning research programs.

The surveillance technique used is an application to a single potential source of health hazards located in many different types of industrial, medical, and research establishments of an environmental health technique developed for a national occupational health surveillance network. This network, designed to estimate the magnitude of the health problem from exposures to chemical and physical agents, has been utilized in six urban areas and in the six metropolitan counties comprising Chicago, Illinois, to assess the potential exposure of several million workers.[1,2]

---

*Present address: Regional Rep., Bar. Occup. Safety & Health, Region V, Dept. H.E.W., 433 West VanBuren Street, Chicago, Illinois 60607.

†Present address: Director, Environmental Health Center, 312 Clark Hall, University of Missouri, Columbia, Missouri 65201.

The laser survey was designed to have relevance to a national occupational health surveillance network. The methodology, which has been reviewed elsewhere,[3,4] consisted of a two-part survey procedure. The first part was an interview with management. Information obtained included the major product or service of the establishment (including the state-assigned numerical code for its Standard Industrial Classification),[5] number of personnel employed both within the total plant or laboratory complex and in the laser operations, extent of general occupational health programs, health services for laser operators, medical incidents attributed to use of lasers, engineering control techniques for laser operations, etc. The general safety program was reviewed, and the health hazards related to the laser operations and the degree of engineering control known to management were recorded.

The second portion of the epidemiologic study consisted of a preliminary walk-through survey of all areas where laser systems were operated. This phase of the study was based primarily on the professional judgment of the industrial hygienists, with additional information being supplied, if necessary, by management about the laser system including make, model, type, beam characteristics, and wavelength, and standard health control operational procedures.

Warning signs, controlled access to laser operations, door interlocks, reflective surfaces, use of safety goggles, and similar health and safety procedures were evaluated.

Consideration was given by the surveyor to all environmental parameters, including chemical and other physical agents, that may have a deleterious effect on the employee or on the community from the use of lasers. It should be noted that this technique is based upon information obtained from management and on the professional judgment of the industrial hygienist making the survey; no measurements or similar evaluations were made.

The establishments surveyed included approximately 25% of all commercially built lasers in the United States,[6] and the sampling is representative of industrial, research, communication, and educational groups known to use lasers. Subscription lists of the nationally circulated trade journal *Laser Focus* were used to obtain the basic list of companies, laboratories, and individuals interested in or operating lasing devices. The data obtained from *Laser Focus* indicated that three states —Massachusetts, New Jersey, and California would probably contain approximately one-third of the commercial lasers in this country. Industrial Laser Buyer's Guides, classified section of metropolitan area telephone directories, and information obtained in some cases by county sanitarians were used to verify this conclusion and to expand the list of establishments using lasers. On the basis of this information and with the cooperation of the health and other official state agencies, an attempt was made to survey 100% of the lasers located in these three states.

Detailed instructions and carefully defined criteria were prepared to guide the surveyors in the techniques of asking questions of management and of evaluating environmental factors relating to laser operations, and to ensure maximum reproducibility of the evaluations made by the various surveyors. The requirement for subjective judgments was eliminated as much as possible, and each surveyor was given a manual containing a complete set of instructions, criteria, and guidelines.

The number of workers potentially at risk to laser energy or harmful agents in the laser areas was determined by estimation. Workers at risk, by definition, did not include other plant or laboratory personnel or similar groups who were not in the laser area, or who did not need access to the laser area to reach their normal work areas.

Where it was determined that workers were potentially exposed to laser energy, toxic agents, or harmful physical energy, the guidelines and criteria in the training manual were used to estimate the effectiveness of the control measures.

The controls or risks of hazards were determined for laser work areas, which were then judged as low-, moderate-, or high-risk areas. The following factors were considered in ranking the laser hazard: energy levels of the

TABLE I

Percent Distribution of Laser Establishments[a]

Employees Size Group	Type of Establishment						
	College Research and Training	Business Services and Research	Manufacturer of Scientific Equipment	Manufacturer of Electronic Equipment	Government	Miscellaneous	Total
1-19	2.5	2.5	3.0	1.0	—	2.0	11.0
20-49	2.0	1.0	3.5	0.5	0.5	1.5	9.0
50-99	1.0	2.0	3.5	2.0	0.5	2.0	11.0
100-249	0.5	4.5	2.0	1.5	—	1.0	9.5
250-499	1.0	2.5	1.5	3.0	0.5	1.0	9.5
500-up	15.0	13.0	4.0	7.0	4.0	7.0	50.0
Total	22.0	25.5	17.5	15.0	5.5	14.5	100.0

[a] Grouped by type of business and number of employees.

lasers; engineering and personal controls: location, congestion, and housekeeping; number of possible exposures; requirements for direct beam viewing; potential for exposure to reflected energy; frequency of use; and other environmental factors.

Examples of factors considered in the different rankings are as follows:

1. Low-risk hazard areas
   a. Low-energy laser; no requirements for direct viewing of the beam; acceptable location with little likelihood of accidental exposure.
   b. Low-energy laser; goggles accessible and used for direct viewing of the beam; acceptable location with only a few workers in the area during laser operations.
   c. High-energy laser in supervised, closed laboratory.
2. Moderate-risk hazard area
   a. Low-energy laser; no attempt to control beam (laser movable and used in several unacceptable locations).
   b. Low-energy laser; laser location easily accessible to untrained personnel.
   c. High-energy laser; good engineering controls and personal protective devices available in open laboratory.
3. High-risk hazard area
   a. High-energy laser; inadequate engineering controls and personal protective devices in an open laboratory.
   b. High-energy laser; poor supervision, with possibility of exposures to several employees.
   c. Low-energy laser; outside work area; possibility of several exposures.

The definition of a high-, moderate-, or low-risk area states only that, in the opinion of the surveyor, the potential risk of exposure is high, moderate, or low and not that any given group of workers is presented exposed or not exposed.

The data are presented only in broad general employment groupings (using as a basis standard industrial classifications), and names of individual establishments are held confidential.

Results

Industries involved in laser use, by and large, are grouped into six major categories as follows:

1. Schools
2. Commercial research organizations
3. Instrument manufacturers
4. Electronic equipment manufacturers
5. Federal government installation and contractors
6. Miscellaneous

A total of 200 establishments constituted the sample included in this survey. The distribution of these establishments by business type and total employment size is shown in Table I. The lasers surveyed in establishments listed in the miscellaneous group included only 14.5% of the sample (Table I). The total number of the nation's commercial lasers at the time of the survey was estimated at 9400.[6] There were 2176 lasers in use in the 200 establishments included in the survey. In these establishments there was a total work force of 458,462 persons, with 279,31 working in the shop, laboratory, or plant (Table II). The majority, or 96%, of the lasers were operated in a single room or build-

TABLE II

Employees and Lasing Devices Surveyed by Type of Establishment[a]

[a]From Powell *et al.*[4]

[illegible]. Although 42% were movable, only 3% were used both in and out of the buildings. Gas lasers were by far the most prevalent—[illegible]% of the total surveyed—and of these, 76% were continuous-wave lasers. Only 2977 employees were classified as laser operators, but because of the nature of their work, 5286 employees had access to or worked in the laser area at some time during the work day (Table II). Seventy-six percent of the lasers, [illegible]% of the laser operators, and 75% of the employees that work in or have access to the laser operational areas are employed in establishments with 500 or more employees.

Medical services provided the employees are widely (Table III). Eighty-nine percent of the establishments had an agreement with a physician to give employees emergency or other medical care, but this varied considerably with the size of the establishment. For example, 95% of all the establishments with 500 or more employees in the sample had such an agreement with a physician, whereas only [illegible]% of the establishments with 1 to 19 employees had made such arrangements. In establishments with over 500 employees, 88% had a nurse in the facility at a designated time, while only 27% of the establishments with 1 to 19 employees had made provisions for such nursing care.

Preplacement physicals were required in 67% of the establishments visited. Eighty-three percent of the organizations with more than 500 employees and 32% of those with 1 to 19 employees required such a physical examination. Those establishments requiring a medical examination of employees prior to assignment as laser operators were considerably smaller in number; only 37% of all the establishments required such a medical examination. Fifty percent of those establishments with over 500 and 9% of those with 1 to 19 employees required a medical examination prior to placement as a laser operator. Of the employees assigned to laser operations, 35% received periodic medical examinations.

Of all standard industrial classifications and employee size group establishments, 48% reported they had made provision for examination of the eyes of laser operators (Table IV). In 96% of these establishments that provided for eye examinations, the examination is given by a physician, and 86% of the examinations are given by an ophthalmologist. About 23%

TABLE III
Percent Distribution of Medical Services[a]

Provision for eye examination of laser operator	23	71	40	40	64	59	48

[a] From Powell *et al.*[4]

of the university and college teaching and research groups had provisions for eye examinations; but only 18% of these establishments had a requirement for a preplacement physical examination for laser operators (Tables III and IV). University, college, and research groups had the lowest percentage for special medical services for laser operators (18% and 23%), yet 64% of the same group reported that they required preplacement physicals for all employees. This same group reported that none had specific requirements for the vision of employees who work in laser areas (Table V). Only 4 of the 36 subgroups by standard industrial classification grouping and employee size reported the same percentage for establishments which had provisions for eye examinations for laser operators (Table IV) as that for establishments which had specific criteria for the vision of laser operators (Table V). These establishments represented a total of 6% of the organizations visited (Table I). Eye damage from operating lasers was reported in 4% of the establishments. Four of the eye damage cases were of permanent injury, only three of which had been previously reported in the literature. Two other establishments reported one case each of temporary eye injury.

Using the criteria developed to evaluate high-risk areas, the industrial hygienist rated 39% of the high-energy rooms as high-risk areas. Although 32% of the people worked in rooms or areas where high-energy lasers were

Total	0	27.4	14.2	26.6	9.0	20.6	17.0

ated. the ratio of the number of people in the room to the number required was 1.59. far the greater percentage (68%) of people worked with low-energy lasers. The tendency was still to permit in the area two and one-half times the number required.

When an employee reported possible exposure to harmful levels of laser energy, 88% of the establishments required a medical examination and 86% conducted a survey or inspection of some type of the area where the [illegible] occurred. However, 95% of both the establishments with more than 500 employees and those with 20 to 49 employees required a medical examination. Fewer establishments in other employee size groups reported that they required such a medical examination. The 1- to 19-employee size group had the lowest number, with 68% of the establishments requiring such examinations.

Approximately 28% of all establishments with about 1600 employees, including laser operators and others who worked in or had access to the laser areas) maintain a medical history of the workers' previous exposures to lasers, infrared, ultraviolet, microwave, or other high-intensity light energy. The remaining workers (about 3700) covered in this survey who have access to the laser work area do not have such medical histories of previous exposures to nonionizing energy maintained by the organization for which they work. A distribution of establishments maintaining such medical histories is shown in Table VI.

The industrial hygienist was required to evaluate each laser installation by giving his opinion of overall controls and procedures according to criteria specifically developed for this survey. The results indicate that 53% of the high-energy lasers and 34% of the low-energy lasers had inadequate or marginal engineering and/or medical control procedures. The arbitrary value used to separate the high- from the low-energy laser placed 30% of the lasers surveyed in the high-energy group and 70% in the low-energy group. Operators of 62% of the high-energy lasers wore some kind of eye protection, as did operators of 25% of the low-energy lasers.

TABLE VI

Percent Distribution of Establishments That Maintain Medical History of Previous Exposures to Nonionizing Energy[a]

Employee Size Group	Type of Establishment: College Research and Training	Business Services and Research	Manufacturer of Scientific Equipment	Manufacturer of Electronic Equipment	Government	Miscellaneous	Total

TABLE VII
Percent Distribution of Establishments with Eye Protection and Controls for Laser Operators

	Type of Establishment						
Controls	College Research and Training	Business Services and Research	Manufacturer of Scientific Equipment	Manufacturer of Electronic Equipment	Government	Miscellaneous	Total
Lasers used with eye protection	19.6	48.0	12.0	7.2	7.7	5.1	99.6
Goggles readily accessible	19.0	50.6	10.4	8.3	6.7	4.7	99.7
Required by company	14.5	46.2	16.0	7.4	10.6	4.9	99.6
Marginal and adequate controls	61	69	80	92	90	60	72

The distribution of eye protection used and required at the various sites can be seen in Table VII.

Warning signs were found in 51% of the rooms, warning lights in 19%, and warning buzzers in 5%. Sixteen percent of the rooms had lights and signs; 3% had lights, but no signs. There was no warning device at all in 45% of the rooms. Of the rooms with no warning devices, 33% had high-energy lasers. Of the 16% with both lights and signs, 66% had high-energy lasers (Table VIII).

Beam enclosure was not a universally used precaution for safe operation of lasers. Only 11% of the high-energy lasers operated with the beam enclosed, and only 8% of the low-energy lasers were so operated.

In general, in 79% of the establishments visited, management felt that there were hazards in working with lasers, but only 61% of the establishments provided training in laser hazards to employees.

Discussion

The industrial hygiene preliminary or walk-through survey, which was the technique employed to evaluate the potential health hazards and their control associated with the use of lasers, is designed primarily to indicate what factors contribute to or most significantly affect the problem under consideration. As such, the surveys are not designed to provide specific information about the design of control measures or the development of health services, but through interpretation by occupational health specialists, they can be use to indicate areas to which additional researc or technical evaluation efforts should be directed.

It is estimated that this survey covere only 23% of the lasers in the United State including home-built lasers. If the data obtained are extrapolated to the entire Unite States, it appears that 25,000 to 30,000 individuals work in or around laser areas an may consequently be exposed to laser energ Of primary concern in evaluating this tot figure is the fact that the work requirem for a significant percentage of the potentia exposed workers do not require that they associated with a laser. This percentage includes employees who have access to or ma pass through uncontrolled laser areas, an those who work in a room where a laser in use, but do not perform any duties directly connected with the laser operation. Th number of workers in the laser area shou be reduced to only those required for t specific operations.

In evaluating the health resources, whic include availability of a physician and nurse and an identifiable occupational hea program with preplacement and perioc physical examinations, the information obtained for laser operations is similar to th obtained in previous occupational health surveys[1,2] which were concerned with any hea hazard in the work environment. Genera results from these occupational health surv indicate that, as the plant size decreases, t

TABLE VIII
Percent Distribution of Establishments with Engineering Controls[a]

[a]From Powell *et al.*[4]

likelihood of the plant's having any components of an identifiable occupational health program also decreases. The laser survey indicated that a high percentage of the laser users were large companies (greater than [illegible] employees), and as a result there was also a high percentage of the companies which had either a partial or a complete employee health program. However, in many cases it was evident that these basic health services, especially in the areas of pre-employment and periodic physical examinations, were not being extended to laser operators. This fact suggests a need for establishments to have and use basic criteria for protecting and/or evaluating the health and safety of laser operators, with special emphasis to the eye.

The application of engineering controls to reduce the potential of exposure to laser energy was not consistent in the establishments surveyed. No one type of laser warning sign was preferred, and the percentage of establishments displaying laser warning signs was low. The use of warning signs, beam enclosures, eye-protective devices, door interlocks, etc., was more likely to be adequate in areas where high-energy lasers were in use. This indicates the need for engineering and medical controls with all laser installations. Guidelines for the application of such control measures, however, should be developed to ensure a more widespread and consistent application.

Although the actual number of reported injuries associated with the use of laser systems is small, those concerned with health and safety cannot afford to become complacent about the problem. It should be noted that the incidents of permanent and temporary injury reported in our survey were obtained on a voluntary basis and reflect the knowledge of such injuries of persons interviewed at the company surveyed. Only three cases of permanent eye damage resulting from the use of laser systems have appeared in the literature, and little information has appeared on temporary damage or on other injuries. This scarcity of recorded information, compared with the number of undocumented reports of laser injury, indicates a need for some type of laser accident reporting and evaluation system. Such a system is required to develop information for meaningful criteria and standards for evaluating the acute and chronic exposure of humans to laser energy. The need for such a system, which might be developed as a Laser Incident Repository, was expressed in the First Conference on Laser Safety, held at the School of Medicine, University of Cincinnati, on January 29–31, 1968.

Summary

The results of this preliminary survey indicate that a number of areas of medical and engineering control should be improved. Moreover, as more laser applications are developed, and as their use shifts from the research laboratory to the industrial plant and to outdoor uses at construction sites the need for more sophisticated control programs will increase. These programs are necessary (1) to protect the industrial worker in the future who may not be knowledgeable about the potential hazards associated with the laser, and (2) to reduce the risk to the general public of being exposed to potentially harmful levels of laser energy. The benefits to derived from such endeavors should ensu a safe environment for laser applications an at the same time, not adversely affect the p tential of lasers for widespread use.

Engineering Control of Electronic Product Radiation

The Department of Environmental Engineering, University of Florida, Gainesville, has announced the expansion of its radiological health training program into the area of electronic product radiation. In effect, the Radiation Control for Health and Safety Act of 1968 passed by the 90th Congress redefined "radiation" as any ionizing or non-ionizing electromagnetic or particulate radiation or any sonic, infrasonic or ultrasonic wave which is emitted as the result of the operation of an electronic circuit. Specifically, microwave devices and lasers are the two items which are currently receiving the most consideration.

Within the department, a new course, Electronic Product Radiation, has been added to the existing radiological health sequence. It covers the evaluation of hazards, the application of standards and the engineering of controls for these types of devices. Microwave devices, survey instruments, lasers and laser accessories are now available for research and teaching.

The program will draw support from a number of segments of the University and from local industries. Microwave engineering courses and assistance in research are available in the Department of Electrical Engineering. A graduate course in laser technology is taught by Electrical Engineering, and a cross-college graduate level course pertaining to the engineering applications of gas lasers has recently been introduced.

A limited number of traineeships will be available to qualified students during the 1970-71 academic year. Persons interested in pursuing graduate study in the area of radiological health should apply at an early date. Further information may be obtained from the Department of Environmental Engineering, University of Florida, Gainesville, Florida, 32601.

ABSTRACT

An electromagnetic radiation survey was conducted on several models and types of video display terminals (VDT) typically used in the communication field. The values obtained for x-ray, ultraviolet, visible, infrared, and radiofrequency levels were considerably below accepted threshold limit values or standards indicating that at the present time, video display terminals of the types surveyed do not present an occupational ocular radiation hazard.

I. INTRODUCTION

Visual display devices, particularly cathode ray tube displays, have been used quite successfully in military and commercial systems for many years. It is with contemporary information display procedures (i.e., graphics and data handling), however, that these visual display devices are finding their greatest application. Video display terminals (VDT) are making inroads into office managerial procedures with their ability to rapidly display letters, numbers, and other symbols. Although exact figures on the number of such devices are not available, it is estimated that between 5 and 10 million units are currently in use.[1] The number is certain to increase within the next few years as the many advantages of the VDT become apparent.

In recent years, inquiries have been received from various user groups concerning the potential hazards associated with these devices. Many VDT operators complain of such symptoms as eyestrain, visual deterioration, headaches, changes in normal visual acuity, and, in some cases, changes in color perception, dulling of sensation of fingertips, nausea, temperature and noise discomfort from equipment, and general fatigue. Recently, the National Institute for Occupational Safety and Health (NIOSH) received a request from the Newspaper Guild and from a prominent newspaper facility to evaluate their VDT for possible electromagnetic radiation hazards to workers. This request was made after opthalmologic examinations revealed bilateral cataracts in two young newspaper employees using VDT.

II. BACKGROUND

Radiation is characterized as energy which is emitted, transmitted, or absorbed in wave or particulate form. Radiation waves consist of electric and magnetic forces which, when disturbed in some manner, produce electromagnetic (EM) radiation. The known EM radiations are grouped into a spectrum arranged by frequency and/or wavelength. The spectrum includes the radio-frequency, microwave, infrared, visible, ultraviolet, gamma, and X-ray regions. The regions are not sharply delineated from each other and, in fact, often overlap. Because of the nature of the physical and biological effects produced, it is convenient to separate these regions as shown in Figure 1.

In conducting a radiation survey, a working knowledge of the source and its characteristics is required. Basically, the VDT operates similarly to a television set. It contains a source of electrons (cathode) and a coated screen (anode) within a specially designed vacuum tube. Under high voltage, electrons are emitted by the electron gun and accelerated toward the anode. The gun scans the screen at a predetermined rate and projects electrons according to an electronically induced signal. When the electrons interact with the screen, which contains a phosphor material, visible radiation is produced and an image is formed. Several types of electromagnetic radiation are produced in a VDT. X-rays can be generated by the cathode ray tube and the shunt regulator tube. Ultraviolet, visible, and infrared radiation are emitted by the phosphor material. Radio-frequency radiation is produced by certain electronic components and circuits. Discussions with VDT desgin engineers indicated that the maximum radio-frequency radiation generated, including harmonics, should not exceed 250 megahertz (MHz).

Since most regions of the electromagnetic spectrum have been implicated as being cataractogenic, it was necessary to monitor across a broad range of frequencies to insure identification of all electro-magnetic radiation emitted by VDT. Luminance measurements were made to document the levels in regard to eyestrain. This report will describe the equipment used, present results of all measurements, discuss the significance of the results with reference to accepted exposure standards, and present conclusions. Mention of company name or product does not constitute endorsement by the National Institute for Occupational Safety and Health.

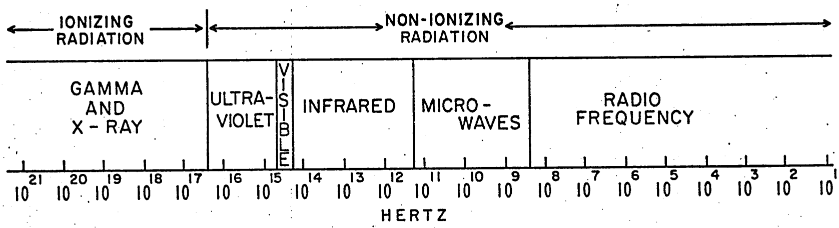

Figure 1. Regions of the electromagnetic spectrum as a function of frequency in Hertz. The division between regions are approximations as an exact division can not be defined.

III. INSTRUMENTATION AND PROCEDURE

Since it was necessary to make measurements in many regions of the electromagnetic spectrum, several types of instruments were used. A brief description of each instrument used in the survey will be given, as well as measurement details.

An EG&G Model 580/585 spectroradiometer was used to detect ultraviolet, visible, and infrared radiation in terms of power per unit area as a function of wavelength. The expression used for such measurement is spectral irradiance, and the unit is Watt per square centimeter per namometer ($W \cdot cm^{-2} \cdot nm^{-1}$). The values obtained are then summed to obtain the total irradiance for the optical region of interest. All measurements were made with this instrument at a distance of 15 centimeters from the face of the VDT screen. A collimating device was attached to the front of the detector and positioned against the screen face to minimize the effect of ambient light. Figure 2 shows the measurement set-up with this instrument.

The instrument used to measure the luminance (brightness) levels of the VDT screen and surrounding luminous environment was a spectral Mini-Spot Photometer. The value obtained with this instrument in footlamberts (fL) represents the luminance observed by an operator regardless of actual distance from the VDT screen face. All measurements with this instrument were made at a distance of one meter.

A Hewlett-Packard Model 5303B Frequency Counter was used to determine the frequency of radio-frequency (RF) radiation up to 525 Megahertz (MHz). To determine the near-field electrical component of RF radiation, it was necessary to use a special meter developed for NIOSH by the National Bureau of Standards, called an EDM-2 Electric Energy Density Meter. The EDM-2 reads out in units of joules per cubic meter ($J \cdot m^{-3}$) in the frequency range from 10–500 MHz.

The instrument used to measure the near field magnetic component of RF radiation was a Narda model 8607 magnetic field detector. This detector indicated units of watts per square centimeter ($W \cdot cm^{-2}$) in the 10–500 MHz region.

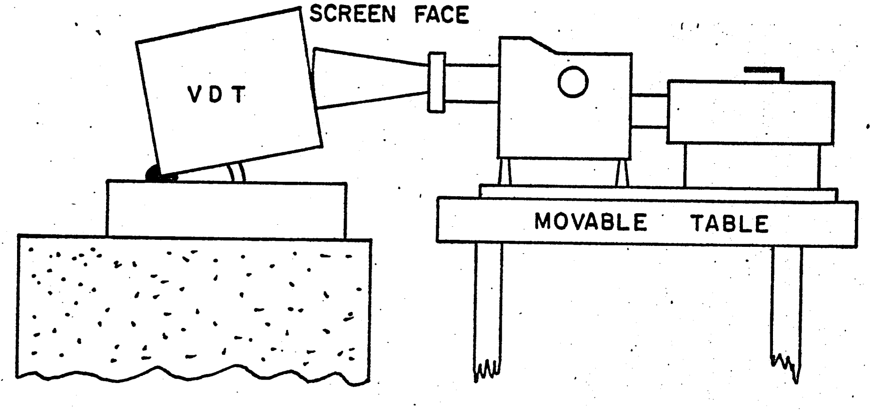

Figure 2. Schematic outline of optical radiation measurement set-up (not to scale)

Measurements of RF radiation using the last three detectors were made by slowly scanning every accessible surface of the VDT with the detectors in contact with the housing. Figure 3 indicates the overall frequency response covered by the instruments used for this evaluation compared to our best estimate of the frequencies emitted by a typical normal operating VDT.

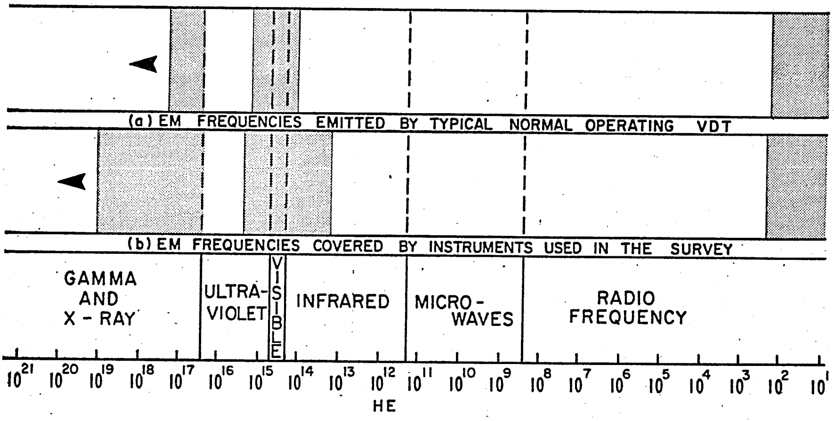

Figure 3. Comparison of EM frequencies emitted by VDT(a) and covered by NIOSH instruments(b) compared to EM spectrum.

IV. RESULTS OF MEASUREMENTS

A. Nonionizing radiation

Using the equipment described in the previous section, radiation measurements of UV, visible, IR, and RF levels were performed on three VDTs located at the newspaper facility. The terminals surveyed were a Telco Model 140 located in a wire service department, a Harris Model 1500A located in a news department, and an Incoterm SPD 10/20 used in a business department. Results of the surveys are presented for each of these three terminals. The first two treminals had been used by the employees with cataracts. In addition, selected measurements were made on numerous other terminals on various floors of the newspaper building.

1. Telco Model 40

The face of the video tube used in this terminal is 19 cm wide by 33 cm high, uses a P–4 phospher, operates at a 15–18 kilovolt (kV) tube potential, and is manufactured by Clinton Electronics, Rockford, Illinois. The terminal was located in a small room apart from other VDTs. The brightness of the tube was adjusted to a maximum and the screen filled with letters and symbols. All room lights were turned off during the survey; however, an unidentified source of electromagnetic interference made measurements difficult on several instruments.

(*a*) *UV measurements.*—The UV spectral irradiance levels for the Telco VDTs are shown in column 1 of Table 1. Notice that all measurements between 200–370 nm were recorded as zero on the 10^{-10} ampere scale of the spectroradiometer. Due to the presence of electromagnetic noise in the area, it was not possible to use the most sensitive spectroradiometer scale. The integrated UV irradiance from 200–400 nm was 2 x 10^{-9} Wcm^{-2}.

(*b*) *Visible and IR measurements.*—No visible or IR radiation was detected using the 10^{10} scale.

TABLE 1.—UV SPECTRAL IRRADIANCE MEASUREMENTS IN UNITS OF 10^{-10} W cm-2. nm^{-2}. OBTAINED FROM THE 3 VDT's SURVEYED IN THIS STUDY

	Telco 40 (1)	Harris 1500A (2)	Incoterm SPD 10/20 (3)
Wavelength (nanometer):			
200	0	0	0
210	0	0	0

390	4.8	.74	2.91
400	14.6	3.65	7.30

(*c*) *RF measurements.*—Certain positions on the screenface of the VDT were emphasized during the electric field survey with the EDM–2 meter. These positions are shown in Figure 4. All readings obtained are shown in Table 2. Notice that a maximum reading of 1.2×10^{-6}J·m^{-3} was observed at the rear surface of the VDT. This RF value was about 25 times greater than the next highest reading. However, when the meter was moved 10 cm away from the rear surface, the RF value dropped to zero even when on the most sensitive scale of 3×10^{-9}J·m^{-3}. The magnetic field measurement using the Narda 8607 meter registered zero on its most sensitive scale of 2×10^{-4}W·cm^{-2}. On this particular VDT, no frequency higher than 2 MHz was recorded. Consequently, none of these readings have real significance since these meters are not designed for measuring frequencies below 10 MHz.

(*d*) *Luminance measurements.*—On the Telco 40 VDT, the brightness values ranged from 1.5 to 2.5 fL for minimum and maximum luminance levels, respectively.

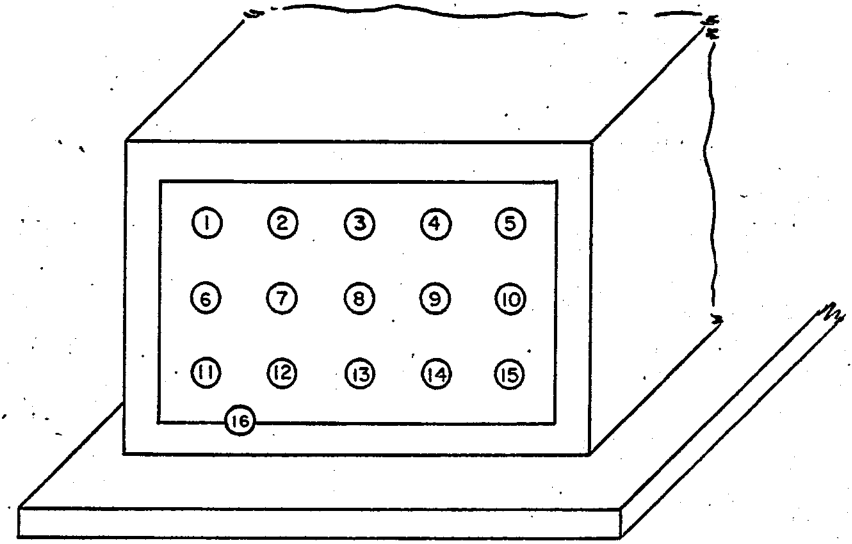

Figure 4. Electric field strength monitoring points on VDT screen face.

2. Harris 1500A

This VDT is one of the more common models used in the newspaper business. The video screen has a square viewing area of 25 cm×25 cm, uses a P-31 phosphor, the video tube operates at a 23-33 kv potential, and is manufactured by Thomas Electronics, Inc., Wayne, New Jersey. As with the first VDT surveyed, the brightness control was adjusted to maximum and the screen filled with a typical message. Because of the size of the room and the numerous ongoing plant operations, it was not possible to eliminate ambient room light during measurements on this unit.

(*a*) *UV measurements.*—The UV spectral irradiance levels for the Harris 1500A are shown in column 2 of Table 1. The integrated UV irradiance from 200 to 300 nm was zero, and from 300-400 nm was $5.1\times10^{-10}W\cdot cm^{-2}$, as measured on the most sensitive scale.

(*b*) *Visible and IR measurements.*—No visible or IR radiation was detected on the most sensitive scale of the spectroradiometer (i.e., 10^{-11} Amperes).

(*c*)*RF measurements.*—A 27 MHz frequency was registered by the frequency counter at the surface of the unit. This signal was not detected when the counter was approximately 12 cms from the unit. The EDM–2 and the Narda 8607 registered zero on their most sensitive scale ($3\times10^{-9}J\cdot m^{-3}$ and $1\times10^{-4}W\cdot cm^{-2}$, respectively) next to the VDT housing. All measurements were conducted in the same manner as with the Telco VDT.

(*d*) *Luminance measurements.*—The luminance values ranged from 2 to 10 fL at the minimum and maximum brightness, respectively.

3. Incoterm SPD 10/20

This VDT has a tube face measuring 16.5 cm wide by 23.9 cm high, uses a P–39 phosphor, operates at a 12–14 kV potential, and is manufactured by Ikegami Electronics, New York City. All measurements were taken at maximum brightness with a filled screen in room light.

(*a*) *UV measurements.*—The UV special irradiance levels for the Incoterm VDT on the most sensitive scale are shown in Column 3 of Table 1. The integrated UV irradiance from 300–400 nm was $1.9\times10^{-9}W\cdot cm^{-2}$.

(*b*) *Visible and IR measurements.*—No visible or IR radiation was detected on the most sensitive scale.

(*c*) *RF measurements.*—A 20 MHz frequency was detected by the frequency counter when held in contact with the VDT housing on the right side. This signal was not detected when the counter was 10 cm from the unit. As in the case of the Harris 1500A both the EDM–2 and Narda 8607 registered zero on their most sensitive scale during the Incoterm survey. All measurements were conducted in the same manner as described previously.

4. Measurements made on other VDT units

RF and luminance measurements obtained on randomly selected VDT units at the newspaper facility generally confirm those values reported for the above three VDT units. Table 3 reflects luminance measurement made on these 22 VDT units. All RF magnetic and electric field measurement, made on these 22 units, were zero on the most sensitive detector scale. In making measurements on a VDT on a higher floor, a RF level of $1\times10^{-3}W\cdot cm^{-2}$ was obtained. With the terminals de-energized, the reading still persisted. From this it was concluded that the source of radiation was not VDT related. Since readings of the same magnitude were obtained in the adjoining computer area, and at nearby windows, it was postulated that signals from nearby TV and radio stations were directly exciting the detectors.

TABLE 3.—ADDITIONAL LUMINANCE MEASUREMENTS OBTAINED FROM RANDOMLY SELECTED VDT UNITS DURING SURVEY

Model	Number of units surveyed	Range of maximum brightness (footlambert)	Range of minimum brightness (footlambert)

Harris 2200	4	3–5	2
IBM 3277	1	7	6
Total	22	3–21	1–6

B. Ionizing Radiation Measurement Results

1. Background

Numerous X-radiation surveys have been reported on various VDT makes and models. The findings in every one of these surveys has revealed that X-ray levels emitted by VDT rarely exceed background. For example, in 1970 and 1972, Dr. Walter Mauderli made measurements on the same Harris 1100 VDT in Florida to determine if radiation levels increase as a function of VDT age.(2) His conclusions were: any aging effect, if it existed at all, "would have the tendency to shift the energy spectrum of the produced X-rays to lower values—thus reducing the penetrating power of the radiation." He also stated that no readings could be found which exceeded the natural background level. In 1973, Mauderli made a radiation survey on a Harris 1500 VDT and concluded that the unit has an X-ray output level at any accessible location which was below 0.02 $\mathrm{mR{\cdot}hr^{-1}}$. Also, in 1973, the U.S. Department of Labor made X-ray measurements on two Harris VDT at United Press International's newsroom in New York City and found radiation levels on the order of background radiation.(3) In 1974, the State of Maryland made an X-ray survey on 74 different VDTs at the Baltimore Sun plant.(4) Their report stated, "In no case did the level found exceed the background radiation level. That is to say, the X-radiation produced by the VDTs was essentially zero."

NIOSH, in 1975, was asked to perform an X-ray survey at the same newspaper facility. The radiation results from this survey were obtained using a Victoreen Model 440 RF/C X-ray survey meter. This meter is shielded against response to RF radiation and measures low energy X-rays in units of milliroentgens per hour ($\mathrm{mR{\cdot}hr^{-1}}$). Background readings taken at frequent intervals ranged from 0.16 to 0.70 $\mathrm{mR{\cdot}hr^{-1}}$. Readings from an internal calibration source were also recorded to insure the meter was functioning properly throughout the measurements.

All measurements were performed by slowly scanning over the display screen, which was filled with letters and symbols, as in a normal operation. Approximately 20% of the VDTs were measured on all 6 sides with the remaining VDTs being surveyed on all sides except the bottom. The gross X-ray levels recorded ranged from 0.12 to 0.85 $\mathrm{mR{\cdot}hr^{-1}}$. The unit with the highest momentary value recorded (0.85 $\mathrm{mR{\cdot}hr^{-1}}$) was rechecked at the conclusion of the survey and a reading of 0.20 $\mathrm{mR{\cdot}hr^{-1}}$ was obtained. When these levels are compared with background readings, it is apparent that no measurable radiation was observed. Table 4 indicates the range of X-ray levels, in $\mathrm{mR{\cdot}hr^{-1}}$, measured on the various VDT types.

In 1977, a major insurance company surveyed 67 VDTs at the same newspaper facility where measurements were made for this study.(5) The maximum X-ray level measured at the screen face from all these units was 0.2 $\mathrm{mR{\cdot}hr^{-1}}$. The VDTs surveyed at that time were made up of the following models: Harris 1500A, Harris 1520, Data Speed 40, Data Disc 66121, and IBM 3277. The insurance company indicated that, since the background ranged from 0.1 to 0.3 mR·hr, then no measurable X-ray radiation was being emitted.

No X-ray measurements were made during the present survey for two reasons. First, the X-ray results from the insurance company and NIOSH measurements indicate no X-ray emission on similar VDTs, both at the same and another newspaper plant; and second, the results of X-ray measurements made by other groups indicated no occupational exposure when properly shielded, as specified by the manufacturers.

TABLE 4.—X-RAY EXPOSURE LEVELS FOR VDT'S

VDT type	Number of units surveyed	Range of X-ray levels ($\mathrm{mR{\cdot}hr^{-1}}$)	
		Maximum	Minimum

Infrarex 1303	11	.22	.14
Background		.70	.16

V. DISCUSSION OF RESULTS

This section discusses results of pertinent electromagnetic radiation measurements and of medical examinations conducted at the newspaper facility.

A. Electromagnetic radiation results

The potential electromagnetic radiation hazards from the VDTs surveyed in this report may be evaluated by comparing the maximum observed reading in any of the regions with currently accepted standards. Table 5 summarizes this information. Observe that, in this table, all values reported are below current safety standards. The use of the symbol ND in the table indicates that energy levels were too low to be detected by the appropriate instrument on the most sensitive scale. All measurements were obtained with the detector probes in contact with the VDT screen face. This means that even these low "emission" levels must be further reduced by geometrical consideration in order to characterize the exposure at the eye position of the operator, typically 0.5 to 1 meter away. Thus, it is appropriate to state that radiation levels 0.5—1 m away from the VDT will be even lower than those values which appear in Table 5.

Therefore, based on the above measurements, the current standards, and present knowledge of biological effects, the VDTs surveyed do not appear capable of producing cataracts or even present an occupational ocular radiation hazard.

TABLE 5.—COMPARISON OF MAXIMUM VDT RADIATION LEVELS MEASURED AT THE SCREEN FACE WITH CURRENTLY ACCEPTED STANDARDS

Radiation region	Maximum VDT measured level	Occupational exposure standard	Reference
Ultraviolet	2×10^{-9} Wcm^{-2}	1×10^{-3} Wcm^{-2}	NIOSH CD (6).
Visible (luminance)	21 fL	2.92×10^{3} fL	ACGIH TLV (7).
Infrared	ND*	10^{-3} Wcm^{-2}	ACGIH TLV (7).
RF—Electric field strength	ND*	2×10^{2} Vm^{-1} 5×10^{-1} Am^{-1}	ANSI (8).
X-ray	0.85 mRhr^{-1}*	2.5 mRhr^{-1}*	OSHA (9).

*Not detectable.
†Includes background level.
‡ Based on the average annual dose limit of 5,000 mR divided by 2,000 working hours per year.

B. Medical results

The two workers with cataracts, one a 35-year-old male and the other a 29-year-old male, were interviewed, and detailed occupational and medical histories were obtained. In addition, their medical records at the newspaper medical department were reviewed. Reports of ophthalmological examinations in 1977 by two opthalmologists were also obtained. In addition, in the case of the 29-year-old male, reports were received of four opthalmological examinations performed between November 1970 and February 1976 by an opthalmologist who is now deceased. The duration of exposure to VDT units at the newspaper by the two workers had been approximately four months for the 35-year-old male and one year for the 29-year-old male. In addition, the 29-year-old worker was exposed during a three month training period (approximately one hour per day for a few days each week) beginning late November 1975. Both of the opthalmologists who examined the two works in 1977 reported finding bilateral posterior cataracts. In addition, the 35-year-old male was noted to have evidence of some retinal degeneration. Attempts to obtain records of previous opthalmological examinations on this worker have not been successful, to date. However, the reports of the previous opthalmological examination on the 29-year-old male showed the first indication of a posterior polar cataract in the right eye on February 26, 1976, a time coinciding with the onset of his continuous daily exposure to the VDT units. (As noted previously, there was a training period of brief intermittent exposure over about three months before he used the units on a regular basis.)

The cataracts found are compatible with those reported from exposure to radiant energy, but they are also compatible with those seen congenitally or those associated with other etiologies, such as diabetes or steroids. However, the workers' medical histories did not disclose any pertinent information to suggest any such etiologies for the cataracts. Since the survey did not indicate any significant occupational electromagnetic radiation levels, the etiology of the cataracts remains undetermined.

Estimates of the incidence of cataract in the United States by age and sex range from 330,000 to 900,000 cases per year[10]. With this many people estimated to develop cataracts, it would not be alarming to find quite a few people developing cataracts in a subset of VDT workers. At present, incidence estimates for bilateral cataracts are not available. Therefore, the above figures have to be viewed conservatively. Interestingly enough, the incidence of cataracts for women is considerably higher than for men.

VI. ADDITIONAL DISCUSSIONS

A. Phosphors

Information can be viewed on a VDT because of the manner in which electrons interact with the phosphor coating present on the screen of a cathode ray tube. Phosphors are chemical substances which exibit fluorescence (i.e., emit visible light) when excited by ultra violet radiation, X-rays, or an electron beam. The amount of visible light produced by a phosphor is proportional to the amount of excitation energy. Every phosphor has a property that allows it to emit light for a very short time after the excitation energy has been removed. This particular property is called persistence, and is extremely important in viewing information presented on the screen. Table 5 indicates some of the characteristics of the phosphors generally used in VDTs, and specifically those encountered in these measurements. The open blocks containing the arrows represent the spectra associated with the given phosphor. The arrows indicate the position of spectra peaks. Notice that the spectra output of these phosphors is limited to a fairly narrow spectral range. Much of the work done in categorizing phosphor properties has been performed by the Joint Election Device Engineering Council (11).

Table 6 confirms our findings that very little UV radiation can be emitted by the VDT. As explained earlier, the level of visible radiation emitted by the phosphors was below the detection limit of the spectroradiometer. Furthermore, the table substantiates the fact that no IR radiation could be detected (since none is emitted). Finally, no measurements were observed which would suggest an increased radiation level of any type as a function of age of VDT. Not every phosphor made is classified in Reference 11; however, most of the phosphors used in VDTs are catalogued and referenced by the organization (11). Using that reference, a spectral energy distribution was made of all phosphors listed, as of November 1975, and is shown in Table 7.

Table 6. Spectral characteristics of phosphors found in VDTs measured in this report (2).

PHOSPHOR DESIGNATION	WAVELENGTH OF PROMINENT SPECTRAL PEAK		SPECTRAL RANGE (nm)
	MAXIMUM	OTHER	
P4 (SULFIDE)	460	560	P 31	520	455	
P 39	525	—	

As can be seen from this list, only three phosphors emit in the IR, while 25 emit in the UV. All IR emitting phosphors in the list produce considerably less than 20% of the total optical spectrum in the IR. With the exceptions of P-15, P-16, and P-47, most of the UV emitting phosphors also produce very little of their total optical spectrum in the UV region (the average is 10-20%). Such a list could be of value in possibly averting any future concern associated with optical radiation.

B. Eyestrain

After reviewing the literature on VDT, it does not appear that any specific occupationally-induced disease has, to date, been documented that implies the VDT as the causative agent. However, complaints of eyestrain (aesthenopia) often are voiced. Eye fatigue and associated symptomatology experienced by people working on VDTs may be similar to the fatigue encountered by workers

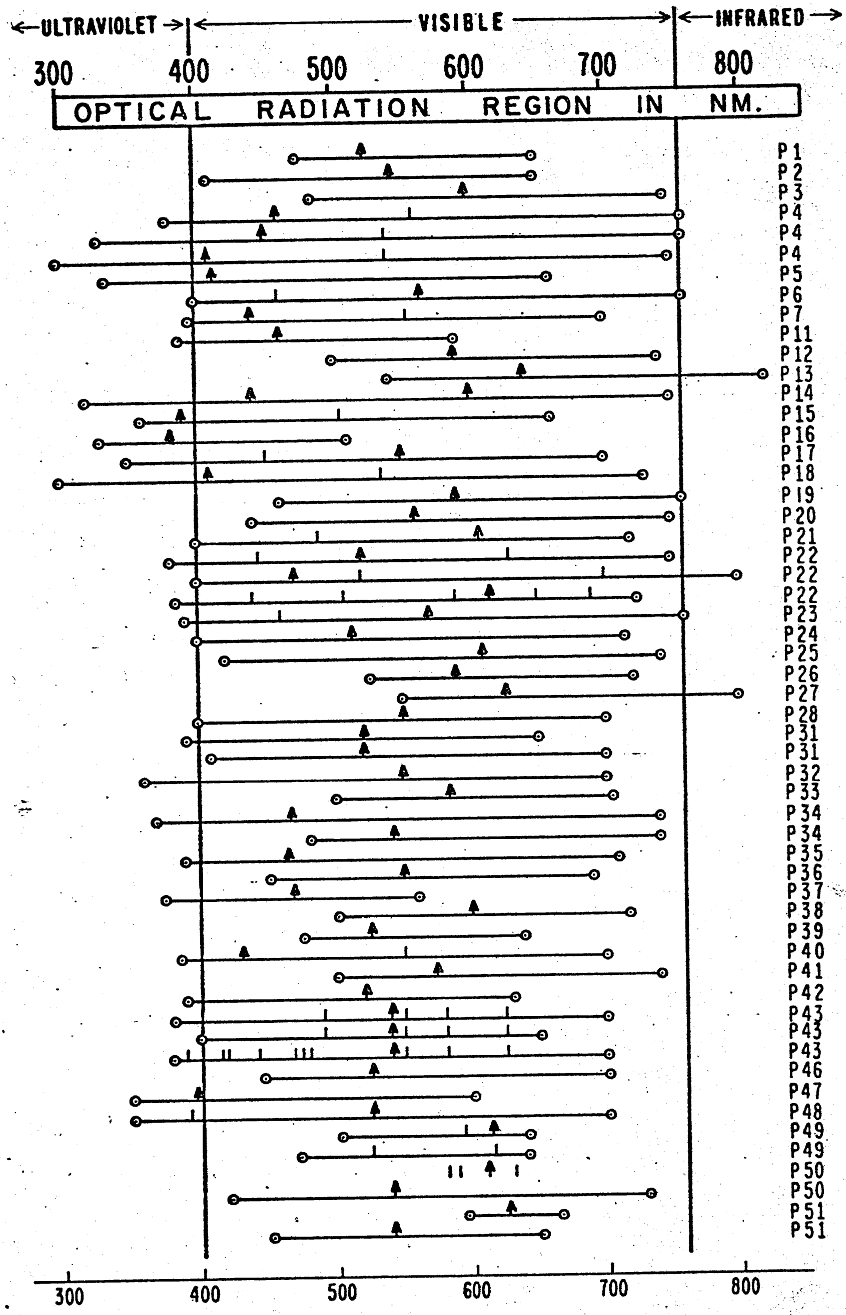

TABLE 7. Estimated spectral energy distribution characterisics of all phosphors modified from JEDEC A/O November 1975.

in other occupations (12). Many factors related to the worker, such as his visual acuity, the task to be done, the VDT itself, the work environment, and the background lighting, will affect the probability that an individual will experience the above symptoms. Obviously work posture, equipment layout, age of worker, length of time spent on VDT, environmental lighting, presence of eye glasses or contact lens, use of antireflection coatings, and latent visual defects are a few factors which will affect the incidence of eye fatigue. However, with many VDTs in use, the number of complaints could be quite large. Attention should be focused in this area on more definitive studies. Some research has been performed by the Armed Services (i.e., air traffic controllers) and by VDT manufacturers. Two excellent reviews of this subject were prepared by Hart (13) and Ostberg (14).

C. Other Measurements

Very little published information was available on VDT radiation levels and measurement techniques, prior to the NIOSH involvement. After obtaining the results presented in this report, and discussing the related problems with many people, several additional measurement exercises to validate these results were conducted by nongovernment facilities. NIOSH has reports from two different facilities examining different VDT models. These reports essentially confirm the data presented in this report. A small difference exists in the numbers obtained in measurements, but in no case did any VDT unit come near exceeding the recommended standard. Frequencies were identified by using a freqency analyzer, with none being detected above a 250 MHz limit, as previously identified by NIOSH.

ATTACHMENT I

MORTALITY AND INDUSTRIAL HYGIENE STUDY OF WORKERS EXPOSED TO MICROWAVES AND RADIO FREQUENCY ENERGY

The past 50 years have brought a rapid proliferation of the uses for electromagnetic radiation. Today electromagnetic radiation emanates from radar, television, communication systems, defense systems, microwave ovens, industrial heat treatment systems and medical diathermy units. In spite of this rapid proliferation of electromagnetic wave length equipment very little research has been conducted in the U.S. to investigate the long-term health effects on low-level microwave radiation on humans. The consequence of undervaluing or misjudging the biologic effects of long-term, low level exposure could become a critical problem for occupational health.

Recent evidence indicates that the development of cancer at certain sites may be associated with exposure to electromagnetic radiation. At a naval air station at Quonset Point, Rhode Island, 3 civilian employees among a group of 8 technicians who were engaged in the overhaul and repair of Tactical Airborne Navigation Equipment (TACAN) have either developed cancer or died of it since 1970. Two of the men (age 31 and 35) developed pancreatic cancer which is very rare considering that 99% of all reported cases occur in people over 40. These 2 men worked side by side at a test bench at Quonset Naval Air Station for several years. NIOSH plans to conduct a retrospective mortality study to further investigate the health effects resulting from long-term, low-level exposure to electromagnetic radiation.

Following site visits at the Naval Air Rework facilities, NIOSH has identified a cohort of workers who may be suitable for inclusion in an epidemiologic study for determining the health effects resulting from long-term, low-level exposure to electromagnetic radiation. This population would consist of all persons enrolled in the electronics apprenticeship training program which has been sponsored by the U.S. Navy since the early 1950's. However, since this cohort will consist of only about 800 individuals, additional walk-through surveys and record assessments will be conducted in both DOD and private industry before a final study population is selected.

Recent NIOH measurements in the TACAN job operation at several naval bases revealed that the present x-ray and microwave radiation levels are currently within the OSHA recommended standards. There is little environmental data available on the past levels of radiation exposure in these job categories.

Protocol For Mortality Study

I. INITIAL RESEARCH

A. Literature searches.
B. Walk through surveys for record assessment and process familiarization.

II. SELECTION OF COHORT

A. Criteria for Selection.
  1. A significant proportion of the population has sufficient latency since onset of exposure.
  2. Suitable demographic and occupational history data for study.
    a. Name
    b. SSN
    c. Date of birth
    d. Sex
    e. Beginning date of employment
    f. Ending date of employment
    g. Detailed occupational history by job and operation (optional)
    h. Last known address (optional)
B. Microfilm all records.

III. BUILD MASTER FILE

A. Code data for computer
B. Verify coding
C. Edit master file
D. Obtain error free master file

IV. VITAL STATUS ASCERTAINMENT

A. Active code alive
B. Inactive
  1. Federal agencies follow-up
  2. State Agency follow-up
  3. Local records follow-up
  4. Case location contract for follow-up

V. MORTALITY AND MORBIDITY INFORMATION

A. Obtain death certificate for those indicated as deceased.

B. Obtain medical information on all deceased individuals through hospital pathology records and medical histories to include smoking.

C. Pathological material will be collected when warranted by investigator to verify diagnosis.

D. Code deaths by the International Classification of Diseases.

VI. ANALYSIS

A. A modified life table analysis to obtain person-years at risk for specific causes of death by five-year age groups and number of years after initial exposure will be developed.

B. Comparisons of observed deaths by specific causes will be made using both United States and local geographic rates to generate the expected.

C. A final report will be written to include mortality, morbidity and environmental data with subsequent recommendations.

INDUSTRIAL HYGIENE PROTOCOL

1. Conduct extensive literature searches regarding physical hazards and specific toxic agents to which workers are exposed to determine current state of knowledge for sampling and analytical methods, past environmental investigations and other related technology and information required to design, conduct and evaluate the results of industrial hygiene studies.

2. Locate industries where the physical hazards or toxic agents under study are used, made or found as by-products. Select industries where representative worker exposures to the specific toxic agent or physical hazard may be expected.

3. Conduct preliminary industrial hygiene surveys, including environmental sampling in preparation for indepth industrial hygiene surveys. Coordinate preliminary surveys with other Sections and Branches within DSHEFS and with other Divisions within NIOSH, as appropriate.

4. Develop detailed written protocol of in-depth industrial hygiene studies including consideration of statistical design; the proper use of the environmental data base; definition of equipment needs to perform the study; delineation of sampling procedures and specification of other related steps required to satisfactorily complete the study.

5. Conduct in-depth industrial hygiene studies in work places including the documentation of past exposures; description of the work procedures and practices; collection of environmental samples; development of job dictionary based on job descriptions in the work place; collection of data on sample sheets for use in environmental data base; and other steps required to produce accurate environmental data.

In-depth study should:

(*a*) Describe the operations and determine the number of workers exposed in the facility. Identify job types for workers and obtain or develop specific job descriptions for each. Obtain raw materials and product lists with respective quantities that relate to worker exposure. Provide photographs and sketches to document existing conditions.

(*b*) Document past and present work practices; industrial hygiene practices, including utilization of protective clothing (i.e. type, frequency of change, laundering practices); protective devices (i.e. respirator usage, type, maintenance); housekeeping practices; shower requirements, eating, smoking and drinking practices in production areas and relevant process or production changes which may relate to past and present worker exposure to the agent under study.

(*c*) Collect personal and area samples to determine the eight (8) hour daily time weighted average and peak concentrations of the agents to which the workers (by job-type) are exposed. Area samples will be taken in areas of suspected high concentrations. Sampling and analysis will be done in a manner consistent with good industrial hygiene practice to provide statistically valid data that are representative of present worker exposures (categorized by different job-types).

(*d*) Describe ventilation systems including design information, appropriate measurements, dates and extent of system changes, and how they relate to past and present worker exposures to the agent under study.

6. Analyze and interpret results from indepth industrial hygiene studies using statistical methodology where appropriate and in terms of job category. Relate environmental findings with data from health effects studies.

7. Prepare detailed technical reports describing the results of literature searches, preliminary industrial hygiene surveys and indepth environmental studies. These reports will be coordinated with other Sections, Branches, and Divisions within DSHEFS.

Senator STEVENSON. Our final witness is Dr. David Rall, Director, National Institute of Environmental Health Sciences, accompanied by Robert Miller and Donald I. McRee.

You may summarize your complete statement if you like.

STATEMENT OF DAVID RALL, DIRECTOR, NATIONAL INSTITUTE OF ENVIRONMENTAL HEALTH SCIENCES; ACCOMPANIED BY DONALD I. McREE, RESEARCH PHYSICIST; AND ROBERT W. MILLER, CHIEF, CLINICAL EPIDEMIOLOGY BRANCH, NATIONAL CANCER INSTITUTE

Dr. RALL. Thank you very much, Mr. Chairman.

I will indeed summarize.

Senator STEVENSON. The full statement will be placed in the record.

Dr. RALL. I am pleased to introduce Dr. Robert Miller, Chief of the Clinical Epidemiology Branch, NCI, and on my left, Dr. Donald McRee, research physicist, National Institute of Environmental Health Sciences.

The NIH is the Nation's principal instrument for both the support and conduct of research in the biomedical sciences.

However, even in such a broadly based effort, there must be concern with the careful selection of research areas.

Thus, when the Atomic Energy Commission, now ERDA, and I gather soon to be the Department of Energy, was created and as part of its mandate began to develop a strong program in biology and medicine related to ionizing radiation, NIH made the decision to move into this area only when it was critical to specific needs of NIH Institutes.

Let me add one historical note. Prior to World War II, the NCI had a strong radiation biology program. Dr. Egon Lorenz, one of the first members of the National Cancer Institute, was a leader in research on the carcinogenic effects of ionizing radiation.

His studies pioneered efforts to understand the biological effects of long-term exposure of large numbers of animals to low doses of environmental pollutants—specifically X-rays.

The first clear demonstration that physicians occupationally exposed to X-rays had a higher incidence of cancer was by Henshaw and

Hawkins of NCI in 1944. This group was joined in the mid-1940's by Dr. Alexander Hollaender. Later on Dr. Hollaender was detailed to the Manhattan project at Oak Ridge and ultimately became, in the early 1950's, the first Director of the Biology Division of the Oak Ridge National Laboratory.

When the NIEHS was created, we reviewed the status of research in environmental factors and identified nonionizing radiation as an area which was receiving inadequate research attention.

Thus, we proposed to develop a program to study the biomedical effects of nonionizing radiation in this area.

Last year the House Committee on Appropriations directed the NIEHS to undertake a study of research needs in environmental health.

This study, undertaken with the participation of more than 80 scientists from Government, industry, and educational institutions, was submitted to the committee in connection with its review of the 1978 budget.

Chapter five of the report addresses the broad issue of physical environmental factors and makes recommendations regarding research needs in this field including nonionizing radiation.

With the committee's permission, I would like to submit that chapter for inclusion in the record at this point.[1]

Senator **Stevenson**. It will be retained in the committee's files.

Dr. **Rall**. A number of the NIH Institutes are conducting research on the use of ionizing radiation as a diagnostic or clinical tool.

For example, the National Institute of Neurological and Communicative Disorders and Stroke has established that computerized axial tomography—CAT—scanners are effective and when used appropriately and with restraint can provide a valuable diagnostic alternative to some other neurological diagnostic procedures which have greater risk associated with their use, such as carotid angiography, cerebral pneumograms, and, to some extent, the isotope brain scan.

The National Cancer Institute supports and conducts research concerning the use of therapy with ionizing radiation. The NCI is studying methods to reduce radiation exposure during diagnostic tests, and is investigating the possible replacements for ionizing radiation diagnostic methods for such problems as brain, breast, and lung tumors.

The National Institute of General Medical Sciences supports a variety of research projects aimed at the development of new radiation detection and imaging systems, development of computerized methods of interpreting radiologic images, and the development of new radio pharmaceuticals.

As indicated earlier, the broad area of environmental and human health effects of ionizing radiation is the primary responsibility of ERDA and the NIH has deferred to that agency in this area.

NCI and NIEHS are, however, conducting and supporting epidemiological studies to determine if groups of patients exposed to diagnostic or therapeutic radiation (for example, radiotherapy for ringworm of the scalp and radioactive iodine thyroid uptake studies) show long-term health effects.

---

[1] See Human Health and the Environment—Some Research Needs, Report of the Second Task Force for Research Planning in Environmental Health Science. DHEW Publication No. NIH 77-1277.

NCI and NIEHS supported the large-scale studies that defined the lung cancer risk for uranium miners.

NCI has provided support for important new programs at the Atomic Bomb Casualty Commission.

In contrast to ionizing radiation, NIH and particularly NIEHS is committed to develop research aimed at broad understanding of the health effects of microwaves.

The NIEHS supports and conducts most of the NIH research in this area. However, due to limited laboratory space and resources, the Institute has only been able to expose small biological systems to a constant field of microwave irradiation.

Because it is important to know the dose of the exposure in order to correlate the incident exposure to the absorbed energy, our scientists have developed systems with well characterized microwave fields.

A refinement of the NIEHS exposure system is that the biological specimen is located inside environmental or constant temperature chambers which allow us to control the temperature and humidity while the biological specimens are being irradiated. This provides the opportunity to look at electromagnetic field effects separated from gross heating of the specimens.

In order to correlate any biological effect with absorbed microwave energy, it is important to accurately characterize the amount of energy that the biological system is exposed to.

Thermocouples or metallic devices used to measure the energy absorption perturb the fields being measured. NIEHS scientists have developed small thermistor probes, liquid crystal fiber optic probes, and infrared thermography which can accurately measure energy being deposited in biological systems, but which do not disturb the system.

Other work we are involved in includes research on the effects of microwaves on teratology (birth defects), fertility and immunology.

On exposing developing embryos to microwave radiation throughout the developmental period a level of 5mW/cm^2, no gross deformities were measured if the temperature was not allowed to rise above normal developmental levels.

However, small but statistically significant effects on hemoglobin and white cells numbers were measured.

In addition, our scientists are investigating basic interaction mechanisms and the effects of microwaves on neural response.

NIEHS is in the process of building a permanent research facility. This facility will contain specially designated laboratory space for our biophysics laboratory. We anticipate that when this becomes available in early 1980, we shall significantly increase our in-house research on the biological effects of nonionizing radiation.

Currently, we are expanding contract research, and, at the Universities of Washington and Utah, we are sponsoring research aimed at determining the effects of long-term, low-level microwave exposure; at the University of California at Los Angeles, work with 60 cycle fields (similar to power line electric fields); and at the Jefferson Medical College research aimed at determining the pre- and post-natal effects of microwave irradiation.

This concludes my summary statement. We shall be happy to answer any questions you may have.

Thank you.

Senator STEVENSON. Thank you.

You mentioned the research on powerline electrical fields. How far along is that?

Dr. RALL. Dr. McRee?

Dr. McREE. The work we are supporting is going into the second year of that research. The research is to determine the behavioral effects of extra low frequency radiation as well as blood chemistries assocated with neurological effects and also the effects on neural tissue.

The University of California has measured the effects of ELF, low-frequency fields of calcium efflux from brain tissue. We are looking at it in terms of powerline fields. We should have some results within the coming year.

Senator STEVENSON. Has similar research, namely on the behavioral effects of microwave radiation, been conducted and reported on in Eastern Europe or Russia?

Dr. RALL. Let me again ask Dr. McRee to answer that. We are part of a U.S./U.S.S.R. medical scientists exchange program and one of the program areas we are interested in is microwave nonionizing radiation research.

We are actively collaborating with the Soviet scientists on this particular area.

Dr. McREE. The Eastern European countries have reported numerous effects on low levels of microwave radiation. There has been an attempt to replicate in the United States—many of the experiments which have been done there.

At the levels that have been reported, in most cases they have not been able to be replicated.

Senator STEVENSON. You mean the results have not been the same or the experiments haven't been done?

Dr. McREE. It has been very difficult to replicate them exactly. You do not have enough information in their papers most of the time to determine exactly what they have done. The results have not been replicated because in many cases the experiment was impossible to be replicated.

However, as part of the U.S./U.S.S.R. agreement, we do have a duplicate project working at field levels of 500 microwatts which is considered by the Soviets to be a high level, which we consider to be a low level.

Using the same test system, behavioral tests, biochemical tests, in order to determine if the methodology is similar—if we do duplicate—we should replicate the effects.

Senator STEVENSON. OK.

Dr. RALL. I think this is the first attempt that I am aware of to sit down with the Eastern European scientists and say exactly what did you do, this is exactly what we are going to do, let's do it the same and see if it comes out the same on both sides of the Atlantic.

Senator STEVENSON. Is the California research being conducted by Ross Adey and Suzanne Bawin?

Dr. McREE. Yes, it is.

Senator STEVENSON. When will we get the results of the collaboration with the Soviets and the Eastern Europeans?

Is that an ongoing, indefinite process or is it going to produce a concrete plan of action?

Dr. MCREE. The cooperative program is a continuing thing with updating an reviewing every 2 years.

The duplication of the project which I am talking about should be completed in the next fiscal year, that is the program was agreed upon for a 2-year period beginning last October. It will be completed within fiscal year 1978.

Senator STEVENSON. Dr. Rall, you said that NIH is concerned with the need to determine the lowest level per dosage of ionizing radiation consistent with a required diagnostic or therapeutic need. You also noted that damage from ionizing radiation can result from cumulative doses given for a variety of purposes.

Other witnesses have testified that the average person's exposure from diagnostic and therapeutic radiation is increasing in the United States.

The first part of the question: Do you agree with that?

Dr. RALL. Yes.

Senator STEVENSON. Well, how seriously do you view this situation and what steps, if any, should be taken to limit the potential health hazards associated with this increasing cumulative exposure? What can you do? What can you do to protect the population?

Dr. RALL. Well, there are a lot of things we can do to assure that the population is exposed to the lowest amount of ionizing radiation.

As I indicated, NIH is trying to develop diagnostic procedures that either do not use ionizing radiation, which of course is the best, or use as low a dose of ionizing radiation as is consistent with interpretative images. This ought, in the long run, to decrease the radiation exposure.

The very delicate issue of when a physician decides to use diagnostic X-ray procedures, whether or not he should do that, is fraught with an enormous number of problems. I think we need to educate our physicians to use X-rays as sparingly as is consistent with good medical practice.

That is very difficult, but that will help cut down the radiation to the population.

Senator STEVENSON. We ought to require public education. I don't think most people are aware of how much they have been exposed to, even for medical purposes.

Dr. RALL. It really has to be both the physician and the public. The physician has to know and the public has to be able to question whether or not this X-ray is necessary.

Senator STEVENSON. I am going to ask the staff to ask the next questions.

Ms. NELSON. Can you comment on the potential correlation of pancreatic cancer and the exposure of Tacan radar operators to microwave radiation?

Yesterday the witness from the Navy stated that any potential correlation was anomalous. Are your epidemiological studies addressing this?

Dr. Rall. I simply think it is too early to say there is a correlation or there isn't. Maybe we ought to look more extensively before we make up our mind.

Dr. Miller, do you have a comment on that?

Dr. Miller. Yes. I think such observations can be considered hypotheses which have to be tested by studying people who are exposed to radar to see if they develop cancer of the pancreas or some other organ more often than usual. Or take people with pancreatic cancers and look back in their histories to see if they were exposed to radar.

Ms. Nelson. Have you planned such a study?

Dr. Miller. No.

Ms. Nelson. Do you know of anyone who does?

Dr. Miller. I do not.

Ms. Nelson. What is the probability of men of that age developing pancreatic cancer? I believe the Tacan operators were in their 30's.

Dr. Miller. I can't give you such a figure. When adult cancers occur early in life, one has an opportunity to determine if there is an environmental cause. This is what happened with respect to DES-induced cancer of the vagina. Neoplasm usually affects elderly women, but when induced by DES, occurs in young women. When such clusters occur, there is a chance to search for an environmental cause.

Dr. Rall. These sorts of observations are very important. In and of themselves they don't prove anything, but as Dr. Miller said, they give you a chance to now ask and answer the question, is there a relationship? It will take future studies to determine that. Statistically it is unlikely.

On the other hand, with just two patients, almost anything can happen. Those very rare occurrences do happen every once in a while.

Senator Stevenson. I have never gotten into a subject on which there has been so much disagreement and so much confessed lack of knowledge. Everything is either being studied or hasn't even started to be studied or is just beginning to be identified as a possible problem.

If you could start from scratch with a clean Federal slate, how would you organize the research and regulatory activities of the Federal Government with respect to radiation?

Dr. Rall. Well, let me just sort of give my personal opinion. I am a pluralist and not a monolithist, if I may make up that word.

The varying demands from an agency concerned about developing energy for the United States are so different from an agency interested in protecting the health of the worker that I see sense in having each one of them have an effective research program.

Clearly by the same token these programs must be strongly and effectively coordinated so each knows what the other is doing, and if and when they duplicate, it is clearly an intentional duplication as we are now trying to do with the Soviets, because the results seem different.

I am also personally convinced that one needs outside independent research organizations independent from either those who do the regulation or those who are promoting a project.

The independent research organizations are the ones that provide the new ideas, the new leads, who bring up the disturbing facts that cast doubt on old regulations. So I think what I am saying is the organization, although it looks messy on a paper full of boxes, may not be that bad.

The coordination in nonionizing radiation that came from the Office of Telecommunications Policy we felt was very useful and enhanced the effectiveness of the limited resources quite significantly.

Senator STEVENSON. OTP?

Dr. RALL. We thought it was very effective.

Senator STEVENSON. How did you find it effective?

Dr. RALL. In coordinating the most reasonably effective use of very limited resources.

I understand, however, from Sunday's Times that as an organization, it may not be around. I would certainly hope that the coordinative function would be retained. I see no reason why it couldn't.

Senator STEVENSON. That story concerned us, too. Is there too much centralization of research in ERDA on responsibility for ionizing radiation?

Dr. RALL. That is very difficult to answer. There are clear advantages in centralization in which you get larger opportunities for interaction.

There are also tendencies for centralized research efforts to become ingrown and not as imaginative as others.

Senator STEVENSON. Or as independent?

Dr. RALL. Yes. I really don't know that I can come up with a clear answer on that.

Senator STEVENSON. Are adequate resources available to NIH now for its research in this field including the nonionizing radiation program that you referred to?

Dr. RALL. We anticipate that there will be. Our permanent facility is under construction. We have designed a special, very large laboratory which can use the sort of complex equipment we need for this sort of research.

If the resources flow to allow us to use that building adequately by early 1980, we should have a much more adequate program than we have now.

Senator STEVENSON. Thank you very much, gentlemen.

Again, we may take the liberty of following up with some written questions.

Dr. RALL. Thank you very much.

[The statement follows:]

STATEMENT OF DAVID P. RALL, M.D., PH. D., DIRECTOR, NATIONAL INSTITUTE OF ENVIRONMENTAL HEALTH SCIENCES ON RADIATION HEALTH AND SAFETY

Mr. Chairman and members of the committee, we appreciate the opportunity to appear before you to discuss the activities of the National Institutes of Health in the fields of ionizing and non-ionizing radiation.

Accompanying me today are Dr. Robert W. Miller, Chief, Clinical Epidemiology Branch, National Cancer Institute; and Dr. Donald I. McRee, Research Physicist, National Institute of Environmental Health Sciences.

INTRODUCTION

The National Institutes of Health is the Nation's principle instrument for both the support and conduct of research in the biomedical sciences and I am convinced that there is no comparable endeavor anywhere in the world in terms either of intensity or diversity of effort. However, even for such a broadly based effort, there must be a continuing concern with the careful selection of research areas in which to work. Thus, when the Atomic Energy Commission (now ERDA) was created and, as part of its mandate, began to develop a strong program in biology and medicine relating to ionizing radiation, the leaders of the NIH made the decision to move into this area only when it was critical to a specific interest of an NIH Institute.

Let me add an historical note. Prior to World War II, the NCI had a strong radiation biology program. Dr. Egon Lorenz, one of the first members of the National Cancer Institute, was a leader in research on the carcinogenic effects of ionizing radiation. His studies pioneered efforts to understand the biological effects of long-term exposure of large numbers of experimental animals to low doses of environmental pollutants—specifically x-rays. The first clear demonstration that physicians occupationally exposed to x-rays had a higher incidence of cancer was by Henshaw and Hawkins of NCI in 1944. This group was joined in the mid-40's by Dr. Alexander Hollaender. Dr. Hollaender was detailed to the Manhattan Project at Oak Ridge and ultimately became in the early 1950's the first Director of the Biology Division of the Oak Ridge National Laboratory. Thus, NIH played a major role in initiating the AEC's biomedical research efforts.

This policy was reviewed and reaffirmed when the National Institute of Environmental Health Sciences was created in 1966. The level of funding for the Biology and Medicine Division of the AEC at that time was comparable to the budgets of a number of NIH Institutes. However, throughout this period the NIH has cooperated with ERDA and utilized the extraordinary resources of a number of the ERDA National Laboratories as places in which to support work of high NIH mission relevance.

Thus, with respect to ionizing radiation, NIH programs focus specifically on ionizing radiation as a factor in disease or therapy rather than as a research area to be addressed in its own right. This contrasts very sharply with the problem of the health effects of non-ionizing radiation. When the NIEHS was created, we reviewed the status of research in environmental factors and identified non-ionizing radiation as an area which was receiving inadequate research attention. Thus, we proposed to develop a program to study the biomedical effects of non-ionizing radiation in this area.

In 1976, the House Committee on Appropriations directed the NIEHS to undertake a study of research needs in environmental health. This study, undertaken with the participation of more than 80 scientists from government, industry, and educational institutions, was submitted to the Committee in connection with its review of the 1978 budget this Winter. Chapter 5 of the report addresses the issue of physical environmental factors and makes recommendations regarding research needs in this field including non-ionizing radiation. With the Committee's permission, I would like to submit that chapter for inclusion in the record at this point.

IONIZING RADIATION

Research Regarding Diagnosis or Clinical Use

A number of the NIH Institutes are conducting research on the use of ionizing radiation as a diagnostic or clinical tool. For example, the National Institute of Neurological and Communicative Disorders and Stroke has established that Computerized Axial Tomography (CAT) scanners are effective and when used appropriately and with restraint can provide a valuable diagnostic alternative to some other neurological diagnostic procedures which have greater risk associated with their use, such as carotid angiography, cerebral pneumograms, and, to some extent, the isotope brain scan.

The National Cancer Institute supports and conducts research concerning the use of therapy with ionizing radiation. The NCI is studying methods to reduce radiation exposure during diagnostic tests, and is investigating the possible replacements for ionizing radiation diagnostic methods for such problems as brain, breast, and lung tumors. The National Institute of General Medical Sciences supports a variety of research projects aimed at the development of new radiation detection and imaging systems, development of computerized methods of interpreting radiologic images, the development of new radio pharmaceuticals, as well as studies on the basic molecular mechanisms of cell damage by ionizing radiation.

Cooperative Relationships with other Research Organizations and Regulatory Agencies

The NIH has a variety of cooperative and liaison activities with the other research and regulatory agencies. These include ERDA, the Bureau of Radiological Health, and the National Science Foundation. The coordinating activities occur both at the policy and working scientist level. As an example, NCI cooperates closely with the Bureau of Radiological Health in its programs. NIH provides peer review of BRH grants. NIGMS staff maintain close liaison with appropriate program officials in ERDA, the Bureau of Radiological Health, and the National Science Foundation regarding overlap of research areas, joint support of conferences, and proposed large-scale human investigations of radiation effects.

Efforts to Establish Diagnostic and Treatment Dosage Levels

The primary objective of much of the research NIH conducts in the area of ionizing radiation is to determine the lowest level of radiation exposure which is consistent with the required diagnostic or therapeutic technique. Since damage from ionizing radiation can result from cumulative doses given for a variety of purposes, it is important that no single dose exceed the minimum level required to accomplish the desired purpose.

Studies to Determine Environmental and Human Health Effects

As indicated earlier, the broad area of environmental and human health ef-cooperates closely with the Bureau of Radiological Health in its program. NIH has deferred to that agency in this area. NCI and NIEHS are, however, conducting and supporting epidemiological studies to determine if groups of patients exposed to diagnostic or therapeutic radiation (for example, radiotherapy for ringworm of the scalp and radioactive iodine thyroid uptake studies) show long-term health effects. NCI and NIEHS supported the large-scale studies that defined the lung cancer risk for uranium miners.

NCI has provided support for important new programs at the Atomic Bomb Casualty Commission (Japanese atomic-bomb survivors).

NONIONIZING RADIATION

In contrast to ionizing radiation, NIH and particularly NIEHS is committed to develop research aimed at broad understanding of the health effects of microwaves.

Cooperative Relationships with other Research Organizations and Regulatory Agencies

The principal group for coordination in this area of activity is the Office of Telecommunications Policy (OTP), through its "Interagency Working Group on the Biological Effects of Non-Ionizing Radiation." This group brings together all concerned Federal agencies. The OTP publishes a complete listing of research projects supported by these organizations. In addition, through the NIEHS, the NIH is represented on ERDA's "Interagency Advisory Committee on Electric Fields Effects for High Voltage Lines." Included on this committee are NIEHS, EPA, Federal Power Commission, Federal Energy Administration, OTP, NSF, the Fish and Wildlife Commission, and the Department of Labor.

Research Regarding Diagnostic or Clinical Use

The NCI is exploring the use of microwaves as an adjunct to the treatment of tumors.

Studies to Determine Environmental and Human Health Effects

The NIEHS supports and conducts most of the NIH research in this area. However, due to limited laboratory space and resources, the Institute has only been able to expose small biological systems to a constant field of microwave irradiation. Because it is important to know the dose of the exposure in order to correlate the incident exposure to the absorbed energy, our scientists have developed systems with well-characterized microwave fields. A refinement of the IEHS exposure system is that the biological specimen is located inside environmental chambers which allow us to control the temperature and humidity while the biological specimens are being irradiated. This provides the opportunity to look at electromagnetic field effects separated from gross heating of the specimens.

In order to correlate any biological effect with absorbed microwave energy, it is important to accurately charatcerize the amount of energy that the biological system is exposed to. Thermocouples or metallic devices used to measure the enenrgy exposure perturb the fields being measured. NIEHS scientists have developed small thermistor probes, liquid crystal fiber optic probes, and infrared thermography which can accurately measure energy being deposited in biological systems, but which do not disturb the system.

In this work, we are using plain-wave far-field exposure systems using horn irradiators, wave-guide exposure systems for cellular studies and isolated nerve preparations, and variable frequency systems with capability between 1 and 10 gHz.

Other work we are involved in includes research on the effects of microwaves on teratology (birth defects), fertility and immunology. On exposing developing embryos to microwave radiation throughout the developmental period to 5mW/cm^2, no gross deformities were measured if the temperature was not allowed to rise above normal developmental levels. However, small but statistically significant effects on hemoglobin and white cells numbers were measured upon hematological examiantion. In addition, scientists are investigating basic interaction mechanisms and the effects of microwaves on neural response. NIEHS is in the process of building our permanent research facility. This contains specially designed laboratory space for our Biophysics Laboratory.

We anticipate that when this becomes available in early 1980, we shall significantly increase our inhouse efforts on the biological effects of non-ionizing radiation. Currently, we are expanding contract research, and, at the Universities of Washington and Utah, the Institute is sponsoring research aimed at determining the effects of long-term, low-level microwave exposure; at the University of California at Los Angeles, work with 60 cycle fields (similar to power line electric fields) ; and at the Jefferson Medical College, research aimed at determining the pre- and post-natal effects of microwave irradiation.

CONCLUSION

There can be little question as to the importance of research on the biological effects of both ionizing and non-ionizing radiation. In the area of non-ionizing radiation, the NIEHS will continue to support research on the health effects of microwaves. Much remains to be learned. In too many cases, we are able to identify and describe what effects radiation has on biological systems; yet do not understand why they occur or by what mechanism of action. This task still stands before us.

My associates and I will be happy to answer any questions you may have.

[The following information was subsequently received for the record:]

QUESTIONS OF THE COMMITTEE AND THE ANSWERS THERETO

Question 1. Several witnesses before the committee have testified that average population exposure from diagnostic medical and dental X-rays is increasing in the United States. How seriously do you view this situation, and what steps might be taken to limit the potential health hazards associated with this increasing exposure? Does adequate regulatory authority exist today to control population exposure to unnecessary diagnostic X-rays?

Answer. Because the U.S. Food and Drug Administration has the regulatory responsibility, as well as the expertise, in this area, we believe it would be better qualified to answer these questions. We are aware, however, that the Bureau of Radiological Health devotes a majority of its resources to the diagnostic ionizing radiation problem.

Question 2. (a). Uncertainty still exists with respect to the validity of the linear hypothesis for estimating population risk from exposure to ionizing radiation. What is the current status of the scientific debate on this question?

Answer. Recently, the HEW Committee to Coordinate Toxicology and Related Programs (for which I serve as Chairman), approved the report (attached) of its Subcommittee on Estimation of Risks of Irreversible, Delayed Toxicity. This report contains the following conclusion concerning the linear model:

"For the purpose of estimating an upper limit of risk associated with a given dose on estimating an upper limit of risk associated with a given risk, assuming no other complication factors, the linear model for low dose extrapolation should be used for incidence data. This should be the case until improved mathematical models based on biological considerations are developed, or in specific instances where sufficient biological information is available to indicate the appropriateness of an alternative model. The development of such improved models should be encouraged."

The report also quoted the BEIR (Biological Effects of Ionizing Radiation) Commission report of 1972 on the somatic effects of ionizing radiation, which recommended:

"At this time, then, the linear hypothesis, which allows the mean tissue dose to be used as the appropriate measure of radiation exposure, provides the only workable approach to numerical estimation of the risk in a population. Further, since there is no means at present of determining the value of the dose-effect slope in the low-dose region of interest, use of linear extrapolation from data obtained at high dose rates may be justified on pragmatic grounds as a basis for risk estimation."

The BEIR Commission, under the direction of the National Research Council of the National Academy of Sciences, has again been reconvened and is in the process of updating its 1972 report.

(*b*) What is your personal opinion as to whether a radiation threshold exists below which no permanent biological damage is associated with radiation exposure?

Answer. I do not believe anyone can answer this question with precision. But in approaching this problem, one must first ask the question: "A threshold for whom?" The human population in the United States, the population we are trying to protect, is a very large, diverse, genetically heterogeneous population, exposed to a variety of carcinogens and other toxic agents. Genetic variability to carcinogenesis is well documented, and we are beginning to understand some of the causes of this variability.

It seems therefore, that instead of saying, "This is the threshold," we really need to say, "This is the threshold for this person or this part of the population." Thus, the question becomes: "Whose threshold and when?"

Further complicating this problem is the fact that rarely is man exposed to radiation alone. He is instead exposed to a whole series of mixtures and compounds all at the same time—all of which may have already put him over whatever threshold might exist for any individual compound or agent. Thus, while it may be possible to establish thresholds in highly controlled laboratory situations, the heterogeneity of the human population in combination with the diverse nature of its exposure makes the application of these thresholds to man almost impossible in practical terms.

Question 3(a). In your prepared comments you state that "ten years ago the area of non-ionizing radiation was identified as an area in which there was a dearth of knowledge and no focal point for the conduct of biological research." What is your view of the situation today?

Answer. Although U.S. research programs to determine and evaluate biological effects of non-ionizing radiation have as yet failed to generate a data base upon which quantitative and scientifically sound microwave radiation standards can be promulgated for the general population, a large amount of research has been carried out during the past ten years at lower power densities than those previously used. This has enabled us to uncover a lot of new needed information, some of which shows no biological effects, and some of which shows biological effects at power levels of 10 mW/cm^2 (milliwatts per square centimeter) and below. Much more work is yet needed to fully evaluate the mechanisms of interaction of microwaves with biological systems.

As in the past, no real focal point exists for the conduct of this research. NIEHS, EPA, NIOSH, BRH, Army, Navy, and Air Force all have ongoing efforts; and each of these agencies determines its own programs. There is no focal point for determining the direction of the total research effort. The Office of Telecommunications Policy has, in the past, performed an important coordination role in this area, but not a decision-making role. This Office, however, has now been dissolved.

(*b*) What are the greatest current research needs in this area?

Answer. The greatest research needs all revolve around the need for determining the effects of long-term, low-level microwave exposure. Specifically, the needs were well summarized by the NIEHS-established Second Task Force on Research Planning in Environmental Health Science which recommended the following:

"1. Epidemiologic and clinical investigations, with emphasis on behavioral, immunologic, and teratologic effects, should be undertaken in groups of workers and others exposed to both high and low power densities of microwave radiation. Special emphasis should be placed on potentially heat-sensitive populations, for example, some elderly people.

2. Chronic low-level studies of animals exposed to power densities approximating the present occupational exposure guide of 10 mW/cm^2 should be undertaken. Emphasis should be placed on possible sensitive test systems, such as the developing embryo, immune defense system, central as well as peripheral nervous system, chromosomes, and possible cumulative effects on the lens of the eye and male reproductive function.

3. Theoretical and experimental research is needed to determine the basic mechanisms of the effects of various radiofrequencies on molecular and cellular components and the loci of interaction as a function of power density and frequency. Biologic systems, such as the brain, heart, ear, and lymphocyte, and model studies, including anthropomorphic models, should be emphasized.

4. Support should be continued for surveys to systematically evaluate the frequencies and intensities of electromagnetic radiation in the environment. The results should be incorporated in the design of laboratory bioeffects studies, particularly chronic studies.

5. Development of exposure systems that yield absorbed power and development of non-perturbing temperature, physiologic, and field probes should be encouraged so that the actual energy absorption and effects can be measured at the point of biologic interest."

(c) Is there adequate coordination of efforts?

Answer. As I mentioned previously, the Office of Telecommunications Policy (OTP) had performed a coordination role in this area. Through establishing the "Interagency Working Group on Biological Effects of Non-Ionizing Radiation," it had brought together representatives of NIEHS, EPA, NIOSH, BRH, VA, ERDA, NASA, CIA, FCC, FAA, NSF, Transportation, Agriculture, Commerce, and Defense (Army, Navy, and Air Force) and had collected a list of all projects undertaken or funded by these agencies. From an information point of view, this effort had been extremely helpful and had provided adequate coordination in terms of letting each organization know what the others are doing. The OTP has now been dissolved. We believe this coordination function is needed and should be maintained at some locus at an appropriately high level in the Executive Branch.

(*d*) Is more funding needed?

Answer. The epidemiologic, clinical, and long-term low-level animal exposure studies needed in this area are expensive. If we were to undertake them, more funding would be needed. However. there is another shortage that must be addressed before we could undertake the necessary work. That is in number of teams of physical scientists and engineers with thorough training and experience in electromagnetic fields and biologists and medical specialists with equally complete backgrounds in the biologic systems under study.

At our own Institute, we currently have only one scientist working in the area of non-ionizing radiation. We are in the process of building a permanent facility which contains specially designed space for our Biophysics Laboratory. When this becomes available in 1980, we hope to be able to significantly increase our inhouse efforts on the biological effects of nonionizing radiation.

(e) Do you perceive real health problems from our lack of knowledge, such as in the regulation of microwave ovens?

Answer. There is presently much public, as well as governmental and scientific, concern for the safety of microwave devices already in use and the possible environmental impact of planned microwave sources in this country. This concern is due in part to the conflicting basis of the U.S. and Soviet exposure guides and in part to the recent reports of biologic effects at power levels less than 10 mW/cm^2.

The United States, France, and West Germany have generally accepted a power density exposure level of 10 mW/cm^2, but the Soviet Union and Poland specify a permissible level of 0.01 mW/cm^2. The fact that there is a factor of 1000 between the accepted U.S. standard and the Eastern European standard results from the different basis used for determining biological effects. The U.S. accepted standard is based primarily on the cooling capability of the body (thus, a thermal effect), whereas the U.S.S.R. and Poland standards are based primarily upon the interaction of microwave fields with the brain and central nervous systems (a neurological or behavioral effect). Before these disagreements in the standards for safe levels of microwave exposures can be resolved, more accurate, well defined experiments must be conducted. At the present time, I do not believe anyone knows what low-level exposure over a five year period will do in terms of biological effects. Nevertheless, if the Soviet research is correct, it indicates there would be some biological effects (primarily neurological effects) resulting from such exposure. So far, it has been difficult for American scientists to reproduce the foreign clinical and laboratory studies because of lack of experimental details in their publications. But our lack of knowledge is such that we cannot rule out the possibility that there is a potential for real health problems. Thus, we must implement the needed research in order to clarify the conflicting data and the resulting conclusions so that a quantitative microwave exposure standard can be established.

Question 4. On page 7 of your prepared comments you referred to research into "the effects of microwaves on teratology, fertility, and immunology." Could you please summarize any results of this research to date, as well as the results of your other studies on basic interaction mechanisms and the effects of microwaves on neutral response?

Answer. In studies to evaluate whether exposure to microwaves during embryonic development has an effect on the developmental process and function of the organism after maturity, we found that exposure of fertilized Japanese quail eggs to a power density of 5mW/cm^2 for the first 12 days of development produces no gross deformtiies or changes in hatchability. Five weeks after hatching, the exposed and unexposed juvenile quail have the same ability to produce antibodies in response to a challenge by foreign cell types—indicating no change in immunological function at that time. At maturity, exposed males—when mated with either control or exposed females—exhibit a ten percent decrease in fertility. Preliminary tests show that at 22 weeks of age female exposed quail exhibit a significant increase in spleen and bursa size and a decrease in liver weight. Experiments will continue to determine why fertility is decreased in exposed males and to evaluate the effects of microwave radiation on body organs. An immunological evaluation will also be made of 22-week-old quail.

Our work on basic interaction mechanisms is concerned with determining how 2450 MHz microwave radiation interacts with biological material at the cellular and macromolecular level. Several studies in the past have reported effects at the cellular level resulting from exposure to 2450 MHz microwave radiation. We undertook similar studies, except we tried to carefully control the temperature, humidity, and other growth conditions in order to eliminate any effects not intrinsically caused by the microwave radiation. Our results showed very few differences between exposed and control samples that could not be explained by the thermal heating of the microwave radiation.

In other work we are attempting to determine the effects of microwave radiation on neurological response. Isolated neurons, such as the sciatic nerves of frogs, are exposed to continuous wave, pulsed, and modulated microwave radiation in the power density range of 1–10 mW/cm^2. Initial experiments show that the exposed frog sciatic nerve, which is simultaneously stimulated to produce an action potential, fatigues at a much faster rate than the control nerve when exposed at 2450 MHz continuous wave microwave radiation. We are now decreasing the power to obtain a threshold for the effect; and we will continue to investigate the mechanism of interaction of the microwaves with the neural specimens.

Question 5.a. What is the current status of the contract research being done at the Universities of Washington and Utah on the effects of long-term, low-level microwave exposure, at the University of California at Los Angeles on sixty cycle fields, and the research at Jefferson on pre- and post-natal effects of irradiation. When were these begun and when will they be completed?

Answer. Work done under contract at the Universities of Washington and Utah is aimed at determining the effects of long-term, low-level microwave exposure on behavior, neurochemistry, and electroencephalograms. Under the contract at Washington (initiated on June 20, 1976 and to be completed on December 20, 1978,) pregnant rats were exposed to 918 MHz continuous wave microwaves at an incident power density of 5mM/cm^2. The exposure was for 20 hours per day for the first 20 days of gestation. No chages in viable offspring or stillborns were observed. Trends toward accelerated development and eye opening in the exposed groups were noted. Growth rates are now being measured. At 90 days of age, acquisition and extinction of conditioned shuttlebox avoidance response will be measured. In addition, exposure of adult rats for 8 hours per day, 7 days a week are now in progress. These exposures will be at both 918 and 2450 MHz and 5mW/cm^2 for a 16 week period. The rats' biochemistry, behavior, and EEGs will be evaluated.

Under the contract at the University of Utah (begun on June 28, 1976 and to be completed on June 27, 1978), methodology and equipment for determining the effects of long-term, low-level exposure to 915 and 2450 MHz microwave radiation on the central nervous system and behavior have been developed. During the next year, the exposure of rats to 915 and 2450 MHz microwave radiation will be carried out. These animals will be monitored for an eight week period after completion of exposure; and biological endpoints relating to biochemistry, behavior, and electroencephalograms will be evaluated.

Under the contract at the University of California at Los Angeles (begun on October 1, 1975 and to be completed on September 30, 1978), environmental field conditions similar to those found in the vicinity of high voltage transmission lines are being simulated; and the effects of these fields on the biological rhythms in rats are being evaluated. Brain tissue, as well as whole-animal, exposures are being performed. So far, an increase in calcium efflux from brain tissue has been measured using low-field intensities. The work will continue to determine if there are other changes in the neurochemistry of brain tissues of cats exposed to these microwave 60-cycle electric fields.

Work is continuing at Thomas Jefferson University to further develop techniques and instrumentation for determining exposure and dosimetric parameters, and for determining the low dose effects of chronic prenatal microwave irradiation on embryonic and fetal development, postnatal development, reproduction capacity, and on the nervous system. An important objective in these studies is to devise methods and models that will enable scientists to discriminate between heat effects as opposed to other types of effects. The grant which supports this work was awarded on June 23, 1975 and terminates on May 31, 1978.

(*b*) Do you support the idea of an epidemiological study to investigate the possibility of the alleged relationship between microwave exposure and pancreatic cancer?

Answer. I believe epidemiological studies are needed to investigate many biological endpoints. However, the problem of eliminating other causal factors has in most cases been impossible because it is difficult to find populations with the same living conditions except for microwave exposure. Thus, I am not convinced an epidemiological study on this topic would be fruitful at this time.

Senator STEVENSON. Thank you.

The committee will recess until tomorrow morning at 10.

[Whereupon, at 1:33 p.m., the hearing was adjourned, to reconvene at 10 a.m. Wednesday, June 29, 1977.]

RADIATION HEALTH AND SAFETY

WEDNESDAY, JUNE 29, 1977

U.S. SENATE,
COMMITTEE ON COMMERCE, SCIENCE, AND TRANSPORTATION,
Washington, D.C.

The subcommittees met at 10:07 a.m. in room 5110 of the Dirksen Senate Office Building, Hon. Adlai Stevenson presiding.

Senator STEVENSON. This is the last day in this series of oversight hearings to evaluate the adequacy of the Federal Government's efforts to protect citizens from the effects of ionizing and nonionizing radiation. It is evident from the record to date that many questions remain unanswered, including whether research on nonionizing radiation is adequate and is responsive to the public health needs; should the licensing of X-ray technicians be made mandatory under Federal law; is coordination between Federal agencies and State programs adequate; are there new areas or technologies such as combustion and conversion of coal that need to be studied to determine if serious radiation problems will exist in the future.

It is hoped today's witnesses will be able to help answer these questions.

We will hear from the Office of Telecommunications Policy, the National Academy of Sciences, the Conference of Radiation Control Program Directors, and the Association of State Radiologic Technologists. Our first witness is Dr. William Thaler, Acting Director, Office of Telecommunications Policy.

STATEMENT OR DR. WILLIAM J. THALER, ACTING DIRECTOR, OFFICE OF TELECOMMUNICATIONS POLICY, EXECUTIVE OFFICE OF THE PRESIDENT; ACCOMPANIED BY JANET HEALER

Dr. THALER. Good morning, Mr. Chairman.

Senator STEVENSON. Good morning.

You are welcome to summarize your statement if you prefer, in which case it will be put in the record.

Dr. THALER. I have with me today Ms. Janet Healer from the Frequency Management Group in my office responsible for the coordination of our work in this area.

OTP's involvement in electromagnetic radiation (EMR) research is an integral part of our responsibility to coordinate telecommunications activities and associated research within the Federal Government. Insuring that the use of nonionizing electromagnetic energy does not harm man or his environment is a major task within that responsibility.

The Federal program, coordinated by OTP, is designed to develop a sound scientific understanding of the interaction of EMR energy with living systems. This will serve as a basis for evaluating possible biological risks from given levels and conditions of EMR and for developing appropriate controls which may be warranted to insure safe and effective use of the spectrum. Five years ago OTP recommended and undertook the coordination of a cooperative multiagency program to investigate biological effects of this energy.

Our efforts involve radio frequency radiation. Like visible light and infrared, these radio waves are nonionizing radiation. Regrettably, the use of the term "radiation" often elicits confusion between this energy and ionizing radiation such as X-rays and nuclear radiation. There are important differences which determine how these different radiations interact with the body and their potential for causing harm. For example, a quantum, or individual bundle, of radiofrequency energy contains far less—approximately a million times less—energy than a quantum of ionizing radiation which can break molecular bonds, produce ionization, and do significant biological damage.

The use of radiofrequency energy has been growing rapidly. Today the radio spectrum is a widely used and an integral part of modern society. It supports such telecommunications services as radio and TV broadcasting, citizen band radio, radars, air and marine navigation and safety systems, and emergency medical services. The spectrum is also used in industrial processing, medical equipment, and consumer products.

We have been working with nonionizing electromagnetic radiation since the days of Hertz in 1890. The first two decades of the 1900's saw the commercial and military uses of this radiation become a reality. The development of more powerful and diverse emitters using a wide range of frequencies during World War II stimulated further advances in this technology and its applications—thus increasing the potential for exposure to EMR. Yet, by the mid-1960's, our knowledge of the biomedical activity of nonionizing radiation was still very limited.

The first major U.S. effort to increase that knowledge between 1957 and 1961 was a Tri-Service program supported by the Department of Defense. It had been known for some time that radiofrequency radiation at sufficiently high levels could cause harmful effects through energy absorption and heating. Studies were conducted in the Tri-Service program which demonstrated some of these harmful effects at power density levels around and above 100 milliwatts per square centimeter. Effects of thermal stress on the body's heat dissipating capability were also studied. These studies contributed to the acceptance of 10 milliwatts per square centimeter, based primarily on thermal considerations, as a permissible exposure limit below which harmful effects would not be expected to occur. This level has since become the basis for present standards in the United States and most Western countries.

Following the Tri-Service program, nonioning electromagnetic radiation research came to a near standstill in the United States, but throughout the 1960's there was an increasing awareness of apparent differences between the United States and the Soviet concepts of the levels at which hazards from nonionizing radiation occurred. U.S. literature showed harmful effects from short exposures a high milliwatt per centimeter levels, while the Eastern literature claimed harmful effects in the low milliwatt per square centimeter and in some cases even the microwatt per square centimeter levels.

Also, the Eastern countries established standards with maximum permissible exposures considerably lower than ours.

Their observations included the effects on the nervous system and behavior, differenes between various frequencies and waveforms, and long-term exposure effects at levels below those associated with measurable heating.

Toward the end of the 1960's there was a convergence of attention and concern by the Government, the scientific community, professional groups, and industry which led to the ANSI standard in 1966 and to the passage of Public Law 90–602 which established the electromagnetic product radiation control program.

In 1967, the Office of Telecommunications Management, OTP's predecessor, initiated efforts to provide a central focus and review process in this area. The first step taken was the establishment of the Electromagnetic Radiation Management Advisory Council, called ERMAC. The ERMAC conducted an extensive review of scientific knowledge, research requirements, the status of research programs, and funding levels. They recommended guidelines, initial research priorities, and increased funding for a coordinated program of investigation among responsible Federal departments and agencies.

The ERMAC is now reviewing its first 5-year plan in light of more recent research and is preparing updated guidelines for future efforts. One of ERMAC's major contributions was the recommendation that OTP, as an independent and impartial entity in the Executive Office, serve as an overview and coordinating body with assistance from the Council. Our role includes emphasizing the importance of this research among other competing agency priorities and attempting to insure that the overall program goals are being adequately addressed.

The basic program objectives continue to be, first, to determine what biological effects radio frequency radiations cause under different conditions of exposure; second, to determine the biological significance of any effect and evaluate the risk in a realistic exposure environment; third, to establish a sound scientific basis for any remedial or control measures which appear needed; and fourth, to insure that U.S. safety criteria provide an adequate margin of safety.

Where do we stand today?

Let me emphasize that the research program to date has identified no positive evidence of harmful effects to man at the levels of exposure normally encountered by the general population.

No crisis has been found to exist. No cause for public alarm has been identified. We must, however, be absolutely certain that nothing has been overlooked and we recommend continued and accelerated pursuit of the necessary research.

Mr. Chairman, I am pleased to report there have been some real accomplishments since this committee's hearings in 1973. First, we have succeeded in creating an effective Executive Office focal point and forum for Government activities related to the biological effects of radiofrequency radiation.

Second, each agency has designated representatives who meet with ERMAC and serve as members of an interdepartmental working group to continually monitor and improve the overall efforts.

Third, relevant research has been identified at the work unit level and organized to facilitate analysis and coordination of research efforts.

Fourth, there has been an increase in exposure facilities available to conduct research over the wide range of frequencies and waveforms of interest.

Fifth, substantial progress has been made in the actual conduct of the research; better techniques and instrumentation have improved our ability to associate biological responses with exposures.

Previous witnesses have elaborated on the specific research and its results. I will not repeat the details. Our office has produced an annual report for the last 4 years which goes into some detail with respect to the specific research and its results. We can certainly make copies of those available to the committee if you don't already have them.

Senator STEVENSON. I believe we already have them.

Dr. THALER. Fine. It is important to note that nonionizing electromagnetic radiation research is a difficult field to work in. It is difficult to quantify how much energy is actually absorbed from the incident radiation due to the complex geometries, the layers of differing electrical properties, the frequency dependence of penetrations, possible resonance effects and so forth.

In the course of the research, biological effects have been observed and reported in experiments with small laboratory animals at levels around and even below 10 milliwatts per square centimeter. These effects include changes in learned behavior or task performance, radiation perception, and apparent alterations in electrophysiological measurements of nervous system activity.

These do not necessarily imply hazards to man for many reasons. For example, differences in size and mass between humans and laboratory animals with respect to frequency and power density and the nature of an effect are among many factors which need to be taken into consideration in assessing or interpreting this research.

Nevertheless, systematic study must continue to be vigorously carried out to determine under what conditions biological effects occur and what their significance is to man. In assessing the impact of this radiation on man, we must first develop a realistic picture of actual exposure environments and the populations involved. You have had testimony from the Department of Defense and from the Environmental Protection Agency on this point.

While the actual measured data is still somewhat limited as the program is continuing, it appears that radiation levels in most environments normally encountered by the general public do not exceed 1 microwatt per square centimeter, which is 10,000 times less than the present occupational safety standard of 10 milliwatts per square centimeter.

Our experience over the past few years has also made it possible for us to identify some of the problems and deficiencies in the program. Let me illustrate some of these problems.

First, electromagnetic radiation research has to compete for resources within each agency against many other programs, some with more urgent priority within the agency's mission.

Second, research requiring relatively large and stable funding, such as experiments with long-term chronic exposures and large epidemiological studies, is beyond the particular resources of any individual agency.

Third, certain types of research, basic research, for example, are not being funded at a high enough level because of the mission orientation of some of the agencies.

Another complicating factor is public apprehension over the question of the safety of microwaves and toher nonionizing electromagnetic radiation. Undertaking a research program in itself can imply that a hazard is either known or suspected.

As the research program begins to produce results, its visibility increases which leads to more publicity in the public press.

Unfortunately, because of the complexity of the subject, the information in the press is sometimes limited, out of context, and difficult to interpret.

The apparent differences in Eastern and Western research and safety standards adds to the confusion.

In summary then, research to date has not demonstrated that any hazard to the general population exists. However, many questions remain unanswered. Resolutions to these questions and experience gained make it possible to identify outstanding research needs and priorities.

These are: First, experiments to investigate effects of long-term relatively low-level exposure; second, studies of people exposed in specific occupations or experimental circumstances; third, increase investment in basic research, including investigations of mechanisms of biological interaction; and fourth, additional development and refinement of techniques for computing comparable doses of radiation, for measuring internal energy fields and energy distribution, and for interpreting laboratory findings to man.

That completes my summary, Mr. Chairman.

Senator STEVENSON. You have spoken interchangeably of EMR and also RF.

As I understand it, EMR can include RF, also microwaves. Is that right?

Dr. THALER. Yes, sir.

Electromagnetic radiation covers the entire spectrum from zero frequency on out through the gamma rays and X-rays. It includes both ionizing and nonionizing radiations.

The RF part of the spectrum is a specific part of the spectrum which lies between a few cycles per second—hertz—well, the radiofrequency is higher, but in general, it is a frequency regime that cuts off just below the visible light. Radiofrequency spectrum lies between—radio, about 3 megahertz up to something on the order of 300 gigahertz. For our purposes we include frequencies between zero hertz and 300 gigahertz.

Senator STEVENSON. It does not include microwaves; is that right?

Dr. THALER. It does include microwaves.

Senator STEVENSON. That's what I want to make clear. Your references to RF, we are talking about microwaves?

Dr. THALER. Yes. Microwaves are a part of the radiofrequency spectrum. They are the shorter or higher frequency radio waves.

Senator STEVENSON. The exposure of the average person to radiation from this source has probably been increasing, hasn't it, in recent years?

Dr. THALER. Yes, Mr. Chairman.

I think due to the increased usage of radiofrequency sources in broadcasting and radars and such. The proliferation of equipment certainly means on the average a general rising level.

Senator STEVENSON. From the growing use of microwaves?

Dr. THALER. Yes, indeed.

Senator STEVENSON. That is a trend which is likely to continue in the future, is it not?

Dr. THALER. I certainly would expect so.

Senator STEVENSON. Could you generalize about that trend? Is it straight up? Up slightly? Or is the exposure radiation from these sources likely to go up—at what—roughly at the same rate as the recent past in the future?

Dr. THALER. Mr. Chairman, I think there will be a continuing increase in the use of these radiations in the radiofrequency range. It is difficult to predict what the far-term future holds, because many of the new technological advances such as coaxial cable and fiber-optics may take many of these sources off the air and restrict them in transmission over these guided media, in which case they will no longer be radiating into the atmosphere.

It is a fairly complicated question.

Yes; I would expect there would be a continuing increase, but I don't think it is particularly a steep-sloped increase.

Senator STEVENSON. After completion of the Tri-Service program, why did research come to a standstill?

Dr. THALER. I am under the impression, Mr. Chairman, that the major hazard that was envisioned at that time was due to the local heating by absorption of microwave energy at levels of 100 milliwatts per square centimeter.

Once that problem appeared to have been adequately addressed by the Tri-Service program, and a safety standard of 10 milliwatts per square centimeter had been reached, there was not an extensive body of literature available indicating any long-term effects of a more subtle nature at lower exposure levels.

It was felt at that time that the pressing problem had been solved, and except for some continuing research by people who were interested in the field, there was no concerted effort to try and extend the work down to lower exposure levels and more subtle effects.

Senator STEVENSON. Do you have any indication about the President's plans for OTP and the proposed reorganization of his office? If OTP is removed from the Executive Office of the President, how will its coordinating role for Federal research on the nonionizing radiation continue?

The third part of that question is how should it continue? How should it be organized?

Dr. THALER. Mr. Chairman, as you know, most of the Executive Office of the President are as much in the dark as the general public as to exactly what the reorganization plan will look like.

In my discussions with the reorganization study teams, I am convinced that they do, in fact, realize the importance of maintaining the major policymaking functions in the telecommunications area somewhere at the level of the Executive Office of the President.

This particular area is a matter of national concern. It cuts across all governmental agency lines. Every Government agency uses telecommunications equipment or services.

I have reason to suspect this subject area will remain at the Executive Office of the President in terms of the direction of the program and that the excellent coordination effort that OTP has effected in the past will not be lost in the transfer to whatever new structure the President decides to initiate in the Executive Office.

Senator STEVENSON. Would it be strengthened if combined with an agency at the same level with a coordinating responsibility for regulation and research on ionizing radiation?

Dr. THALER. Mr. Chairman, I would not consider that to be a particularly helpful move. The technical problems involved in treating nonionizing electromagnetic radiation, biological effects, are completely different than the problems involved in looking at the effects of ionizing radiation.

The mechanisms are different. The range of the spectrum is different. The technological skills required to investigate this area are different.

My feeling is that the subject is important enough in its own right not to get married in with an effort that has been going on for 30 years in ionizing radiation, which has developed a vast body of information and expertise.

My fear is it might become a second-class citizen in such an environment. I think it deserves a more forceful continuation of our existing programs.

Senator STEVENSON. You indicated that the funds to which you have access are not adequate.

What would be adequate?

Dr. THALER. Mr. Chairman, trying to estimate funds is a difficult problem.

If you approach it from the truly scientific basis and say what kind of programs would you like to support, you can come up with an estimate that, in my opinion, would be something on the order of two or three times the funds that are now expended in this area.

Senator STEVENSON. You indicated $9 million?

Dr. THALER. The present level of expenditure is $9 million.

The problem, of course, is that all the funds that the taxpayers put in have to be allocated across the board on the basis of priorities.

I think one of the major tests that OTP sees for itself is to try and keep this interest we have generated in the program at least at the level it is now, and hopefully encourage agencies who make their funding estimates to attempt to get OMB to approve additional funding. Hopefully we can bring this matter under closer scrutiny by the White House staff to try to convince the President to believe that this is a matter that requires additional funding and can still be done and balanced off within his overall budget priorities.

That's our basic problem.

Senator STEVENSON. The $9 million goes to the various agencies?

Dr. THALER. Yes.

Our sole function is to coordinate and integrate research programs and try to encourage the agencies to put the funding level into their budgets that the coordination group determines is the proper level for research.

Senator STEVENSON. How much authority do you have to actually allocate the $9 million?

Dr. THALER. We do not have any authority to program or allocate funds in this area. We can recommend to the agenices through our ERMAC processes what we think their funding level should be in order to satisfy the goals and objectives that ERMAC and the interdepartmental working group have established.

They then have to weigh our recommendations against all the competing priorities they have, the constraints they have from the budget generation process and come up with an optimum amount—an adequate amount to fulfill our objectives.

Senator STEVENSON. Could you recommend, in addition to increased funding, increased authority over the allocation of those funds in OTP or its successor? Should that coordinating agency have more than just a coordinating influence on these agencies?

If so, what should it be?

Dr. THALER. Mr. Chairman, that would be helpful in the sense it might allow us to generate more funds to get into the battle.

Actually, the present process, which has been, I think, a very fruitful, cooperative effort between all of the agencies and OTP as the coordinator, is an endeavor that I would not like to see caught up in the tensions involved in their feeling that we were imposing our will on their efforts.

Everyone has done, I think, the best that they could under the budget constraints to come up with the funds.

I really think our coordination efforts have been reasonably successful. My hope is that I can raise this concern at the Presidential level to the point where the agencies may be permitted to make decisions on the priorities for their fundings that will enhance support in this area.

Senator STEVENSON. Senator Schmitt?

Senator SCHMITT. Thank you, Mr. Chairman. I apologize to you, sir, for missing your testimony. I quickly scanned portions of it.

In the work of your group, have you examined and compiled the biomedical research that is going on in the country on the effect of various levels of nonionizing radiation on plant growth, animal response and so on?

Could you summarize the general areas of research and tell us whether there are any significant effects being noted?

Dr. THALER. I would like to ask Ms. Healer to respond to that question.

Ms. HEALER. Our office does not conduct research directly, but we do—with our advisory council and in the interagency forum—continually review the results of research as they are forthcoming.

Senator SCHMITT. As published, or as results actually are obtained?

Ms. HEALER. Both. We hold seminars, for example, in selected research areas. For example, on research into nervous system and behavioral effects, measurements of environmental levels, and so forth.

In addition, we also review research on an agency basis. We do continually try to maintain reviews of research, as it is being conducted.

Senator SCHMITT. Let's take microwaves, for example. What is the status of animal response to various levels of microwave radiation?

Ms. HEALER. That is a very broad question.

Senator SCHMITT. I realize that. Can you give the committee any insight?

Ms. HEALER. This research is conducted to look for the whole range of possible human or living system response to radiofrequency—including microwave—radiation.

A number of different end points are being looked at.

Some of these are derived from the published Soviet literature and the kinds of effects they report.

Therefore, there is a good deal of research investigating potential nervous system and behavioral responses, in a variety of animals and at a variety of frequencies. We had at the outset recommended some frequency and biological priorities. I think the research efforts follows those guidelines.

Other biological parameters are also being investigated. We have seen changes in some of these biological parameters. However, it is still early to say what the significance of these changes are for the animal in some cases and certainly for man.

Dr. Thaler mentioned some of these effects in his testimony. For example, we have seen that animals seem to be able to perceive the presence of microwaves or radio. These experiments involve a divided box—referred to as a shuttle box. One side is illuminated with microwaves and the other is shielded so that it is not. The animal is free to spend its time on either side of the chamber.

It has been observed that animals tend to spend more of their time in the shielded portion of the chamber, rather than the side where the microwaves are. It is difficult to determine at this stage the significance of this finding for man. Such observations are being investigated further.

Senator SCHMITT. Your recommendations are made to the National Science Foundation and other agencies which are funding various types of research?

Ms. HEALER. I am sorry. I didn't hear the question.

Senator SCHMITT. You said you made recommendations on certain radiofrequency areas which should be investigated. Are those recommendations made to the other Government agencies to guide their research programs?

Ms. HEALER. Yes. They are recommendations for the overall Federal Government program.

Senator SCHMITT. Are there any recent summaries of research results in biological responses which would be useful to submit to the committee for the record?

Ms. HEALER. Yes—I think some have been submitted already to the committee. There are many such reviews. Our office summarizes program activities annually. This is an overview kind of summary. Our reports also contain reference to specific ongoing research and to scientific publications to try to give feeling for what kinds of research different agencies are doing.

A number of individuals and groups, such as the World Health Organization and ANSI (a widely recognized professional body), among others, have also published reviews and research recommendations.

Senator SCHMITT. Does the committee have an up-to-date summary of the most recent measurements?

Ms. HEALER. Yes.

Senator SCHMITT. You mentioned the Soviet research efforts in this area. Generally, they have had somewhat different safety standards relative, for example, to microwave radiation. Would you care to comment on that difference and the reason for it?

Ms. HEALER. I wish I could tell you the specific reasons for it. I can say this: first of all, I think it is important to remember that all safety standards—in any country—are not set at the threshold where harmful effects occur.

In fact, in their design, all safety standards are intended to incorporate a margin of safety below the lowest level at which it is felt effects might occur.

They are also based upon the best available information at any given time. As such, they are manmade criteria and should not be blindly worshipped. They should always be subject to review as new knowledge becomes available.

This, in fact, is happening not just in this country, but also in the Soviet Union at the present time.

We don't know the precise reasons or the basis for the Soviet standards, but there are indications that to some extent the differences may, in part, be due to differences in interpretation of effects and what one considers a hazard. All effects, of course, are not necessarily hazards.

There may also be differences in approach in the development of safety standards.

Until recently, there has been very little contact between East and West in this area. There hasn't been an opportunity to try to resolve these differences.

Recently, under one of the U.S.–U.S.S.R. collaborative agreements, as mentioned by Dr. Rall of NIEHS, there has been developed a collaborative research program in the microwave area.

It is a small effort at this stage, but we are very hopeful that this exchange will be helpful. It does include a rather exciting aspect, I think. That is, an opportunity to conduct a duplicative experiment which we are going to try to make as precisely alike as possible.

We hope this will give us an opportunity to get a better understanding as to the basis for some of these differences.

Senator SCHMITT. In the microwave area, they basically set a lower standard or a lower threshold?

Ms. HEALER. Yes; they have. It is an apparent factor of 1,000 lower.

Senator SCHMITT. Has your office been involved at all in the discussions between ERDA and NASA concerning satellite power systems and the use of microwaves to transmit large amounts of power from space to Earth?

Ms. HEALER. We have followed the development of this concept. OTP, in fact, has followed it for reasons of spectrum support. We have been briefed in the ERMAC and also in the scientific working group on proposed systems and associated research.

I believe the biological considerations of what kinds of research might need to be done to support that activity are still in the planning stages.

I am not personally certain where that responsibility finally lies. However, we have heard from both NASA and ERDA on that subject.

Senator SCHMITT. Do you have any plans to get further involved in this discussion? The generation of power in space is one of the options for the early part of the next century. It is one I think the administration should be paying some attention to, with the emphasis on the use of solar energy for conserving energy resources.

Dr. THALER. We certainly will. Our responsibility in the telecommunications area is very broad. We certainly would consider that. We would have to allocate the frequency to begin with, because it would be a Government activity.

At least if a private corporation does it, we would have to advise the FCC. We certainly will get more and more involved in considerations of that whole area.

Senator SCHMITT. Would you get involved in considerations of safeguards to prevent any misapplication of large amounts of microwave energy from space?

Dr. THALER. I think, basically, our role in that area would be to cooperate with those agencies that have the regular responsibilities for safety, the EPA, the Bureau of Radiological Health, and so on.

We certainly do cooperate with them and make our comments on these specific areas under question to try to reach an accommodation that will be supportive of our efforts to discharge our responsibilities in this area and will be in line with the present up-to-date state of the art in trying to predict potential risks and hazards.

Senator SCHMITT. Do you have any feeling at the present time as to what is an acceptable level for broad microwave transmission at the Earth's surface? Or do you feel it is too early to say whether any level will be acceptable?

Dr. THALER. Well, Mr. Schmitt, as I stated in my testimony, there is no evidence that at power levels to which the general population is now exposed there is any risk or hazard. There just simply is no evidence.

I have looked at the Soviet literature in this area.

I find it very confusing. If I may say so, as a physicist, it is an interdisciplinary area where much of the initial work has been done largely by the biologists.

I think you are a physicist, too, aren't you?

Senator SCHMITT. I am a geologist. I have some background in this area. The same confusion exists in geology.

Dr. THALER. The kinds of parameters that, as a physicist, I would look for in terms of a specific statement of the frequencies, specific statement of the power level, what kinds of instrumentation were used to measure these levels, and so on, is so fuzzy.

That's been one of the reasons why it has been almost impossible to duplicate the Russian experiments in this country.

Senator SCHMITT. There is a very strong tendency to publish results and not technique?

Dr. THALER. Right. That complicates the situation. This whole area of low-level long-term exposure is an area that is exceedingly difficult in a multidisciplinary field like that. We really do need to get more work between the various disciplines involved in a cooperative effort in this area.

We have to get the engineers, the physicists, the medical people to talk the same language.

I have done research in biophysics. The hardest part is to get the biologists to understand what the physicists' terms mean and what kinds of standards we require in our experimentation and vice versa.

Janet says that maybe one of the biggest accomplishments we have made in our program of coordination is actually getting these disparate disciplines more closely involved in a cooperative effort.

Senator SCHMITT. One final question: Have any of your activities taken you into the area of high intensity magnetic fields?

Ms. HEALER. Not per se. We are interested, of course, in the electric and the magnetic components of the electromagnetic field in terms of the possible differences in their biological effects. Not high intensity magnetic fields per se as you mean.

Dr. THALER. I must say one of my faculty at the university from which I came is involved in this area using superconductive magnets. He has noticed some very interesting biological effects of these intense magnetic fields. Of course, a person would never normally be exposed to such a field.

Senator SCHMITT. Not yet anyway.

Dr. THALER. Not yet. In the future, who knows? It may be an area of considerable interest.

Senator SCHMITT. There are a number of futuristic energy conversion systems which could potentially use intense magnetic fields. Again, it is something that I hope you will not ignore completely.

Dr. THALER. We will be there.

Senator SCHMITT. In recommending some level of research in the country, through Government agencies, it is important.

Dr THALER. Yes; indeed.

Senator SCHMITT. Magnetohydrodynamics, and a number of other concepts, including fusion, will require those intense fields. Hopefully they will be focused fields. Nevertheless, people working with them will be exposed to higher levels than normal. I think there is fairly persuasive biological evidence that magnetic fields do have some influence on how life develops.

Dr. THALER. Yes indeed.

Senator SCHMITT. Thank you, Mr. Chairman.

Senator STEVENSON. One more question.

Do you think that enough research has been conducted now to justify funding of a major study on the effects of nonionizing radiation, a study similar to the National Academy of Science's BEIR report?

Dr. THALER. Mr. Chairman, my feeling is that at the moment we are nowhere near the level of information that would make a BEIR type study reasonable. If you look at the expenditures over the last 30 years in the field of ionizing radiation, the body of literature that has been generated, it is just of staggering proportions. The amount of work, literature that we have so far managed to generate is relatively small compared to that effort.

I do feel, however, that a study by an independent body like the National Academy of Sciences could be very useful in focusing on two areas. First of all, a general kind of independent review of what has been done, but more important, as Mr. Schmitt mentioned, I am also concerned about what the future holds with new techniques, new equipments coming to the fore.

I don't think this has been done yet. Somebody ought to look at present technologies and emerging technologies and try to forecast what kind of levels we might expect by the year 2000. I think that would be a very worthwhile endeavor that the National Academy would probably be very capable of doing.

Senator STEVENSON. That was my next question. The National Academy would be the appropriate place?

Dr. THALER. It seems to me it is certainly one of the places that could draw together the necessary expertise in the various disciplinary fields to give this thing a thorough going over.

Senator STEVENSON. If there are no further questions, thank you very much.

Dr. THALER. Thank you, Mr. Chairman.

[The statement follows:]

STATEMENT OF WILLIAM J. THALER, ACTING DIRECTOR, OFFICE OF TELECOMMUNICATIONS POLICY, EXECUTIVE OFFICE OF THE PRESIDENT

It is a pleasure to be here today to discuss the Government's program to assess the biological effects of nonionizing electromagnetic radiation.

OTP's involvement in electromagnetic radiation research stems from the dependency of telecommunications on the use of the radio frequency spectrum. The Director of OTP is responsible for advising the President on national telecommunications policy and on the Federal Government's use of telecommunications. An important component of these responsibilities is OTP's mission to coordinate telecommunications activities and associated research and to develop programs which will promote the use of telecommunications in the public interest. Insuring that the use of nonionizing electromagnetic (EMR) energy does not harm man or his environment is a integral part of this responsibility. OTP oversees a valuable national resource—the EMR spectrum—and is also interested in seeing that the vital and beneficial services the spectrum makes possible are not unnecessarily curtailed or impaired.

The Federal program, coordinated by OTP, is designed to develop a sound scientific understanding of the interaction of EMR energy with living systems. This will serve as a basis for evaluating possible biological risks of various levels and conditions of EMR and for developing appropriate controls which may be warranted to insure safe and effective use of the spectrum. Since its formation, this Office has had a vital interest in a strong Federal research program in this area. We recommended 5 years ago and undertook the coordination of a cooperative multiagency program to investigate biological effects of this energy so that there would be no unintended or unknown effects.

Our efforts involve radio-frequency radiation (i.e., 0–300ghz). Like visible light and infrared, these radiowaves are nonionizing radiation. Regrettably, the use of the term "radiation" often elicits confusion between this energy and ionizing radiation such as X-rays and nuclear radiation. However, there are important differences which determine how these different radiations interact with the body and their potential for causing harm. For example, a quantum, or individual bundle, if radio frequency energy contains far less (i.e., approximately a million times less) energy than a quantum of ionizing radiation which can break molecular bonds, produce ionization and do significant biological damage.

The use of radio-frequency energy has been growing rapidly. Today the radio spectrum is a widely used and integral part of modern society. It supports such telecommunications services as radio and TV broadcasting, citizen band radio, radars, air and marine navigation and safety systems, and emergency medical services. The spectrum also is used in industrial processing, medical equipment, and consumer products.

We have been working with nonionizing electromagnetic radiation since the days of Hertz in 1890. The first two decades of the 1900's saw the commercial and military uses of this radiation become a reality. The development of more powerful and diverse emitters using a wide range of frequencies during World War II stimulated further advances in this technology and its applications--thus increasing the potential for exposure to EMR. Yet, by the mid-1960's, our knowledge of the biomedical activity of nonionizing radiation was still very limited.

The major U.S. effort to increase that knowledge between 1957 and 1961 was a Tri-Service Program supported by the Department of Defense. It had been known for some time that radio-frequency radiation at sufficiently high levels could cause harmful effects through energy absorption and heating. Studies were conducted in the Tri-Service Program which demonstrated some of these harmful effects at power density levels around and above 100 mW/cm^2. Effects of thermal stress on the body's heat dissipating capability were also studied. These studies contributed to the acceptance of 10 mW/cm^2, based primarily on thermal considerations, as a permissible exposure limit below which harmful effects would not be expected to occur. This level has since become the basis for present standards in the U.S. and most Western countries.

Following the Tri-Service Program, non-ionizing EMR research came to a near standstill in the U.S., with the exception of a few isolated studies which included some investigation of biological effects at lower radiation levels. In this period, there was an increasing awareness of apparent differences between United States and Soviet concepts of the levels at which hazards from non-ionizing radiations occurred. While our literature showed harmful effects from short exposures at high milliwatt levels, the Eastern literature claimed harmful effects in the range of several milliwatts/cm^2, and in some cases, even microwatt/cm^2 levels. Also, the Eastern countries had established standards with maximum permissible exposures considerably lower than ours. They reported a wide range of observations (for example, effects on the nervous system and behavior), differences between various frequencies and waveforms (e.g., pulsed vs. continuous wave), and effects from lengthy exposures to levels below those generally associated with measurable or significant heating. We had no comparable research or basis for comparison and evaluation. Their publications frequently did not contain full information nor has there been a clear statement of the basis for their standards. However, our interest has led us to make a principal focus of our research since the mid-1960's the question of whether or not biological effects can be caused by EMR mechanisms of interaction with the body other than heating (nonthermal). Also, regardless of the mechanism involved, we want to know whether harmful effects can occur over a wide range of EMR conditions including lower radiation levels than we had previously anticipated. The Soviet research has been used to provide some initial guidelines in determining our present research priorities.

Toward the end of the 1960's there was a convergence of attention and concern by the Government, the scientific community, professional groups and industry on the biological effects of nonionizing radiation. In 1966, for example, the ANSI standard was issued; in 1968 a major industry report pointed to the need for a "central interdisciplinary coordinating body" in the "side effects" area, and Public Law 90-602 was enacted.

In 1967 the Office of Telecommunications Management, the predecessor to OTP, held discussions with academic, industrial and government personnel and initiated efforts to provide a central focus and review in this area. As a first step, the Electromagnetic Radiation Management Advisory Council (ERMAC) was established. It was made up of individuals with expertise in the various pertinent technical disciplines—biomedical and physical sciences and engineering—to advise and make recommendations on the adequate control of undesirable "side effects" associated with the use of the spectrum. The Council conducted an extensive review of scientific knowledge, requirements, and the status of research programs and funding. They recommended guidelines, initial research priorities, a framework for studies, and increased funding for a coordinated program of investigation among responsible Federal departments and agencies.

The 1971 ERMAC report reviewed the background and rationale for this research and emphasized its importance with remarkable foresight, for it has continued to provide valuable and comprehensive guidelines for research in this area. As a basis for determining future research requirements, the ERMAC continually reviews program activities on the growing state of knowledge of health effects. The Council is now in the process of reviewing its first five year plan in light of more recent research and is preparing updated guidelines for future efforts.

The research program was structured to take advantage of existing agency responsibilities and capabilities—although no single agency has this area as a principal mission, several departments and agencies do have relevant missions. Agency missions and operational needs were viewed as incentives to utilize their technical capabilities to conduct research. However, research was fragmented, funding was limited, and there was little, if any, interagency interaction. In order to use available resources effectively without distorting the priority of this research, ERMAC recommended that OTP, as an independent and impartial entity in the Executive Office, serve as an overview and coordinating body, with assistance from the Council. The OTP role includes emphasizing the importance of this research priority among other competing agency priorities, and attempting to ensure that the overall program goals are being adequately addressed.

At its inception, the ERMAC recommended program expenditures of approximately $10–15 million/year over a 5-year period for a coordinated Government-wide research effort. This recommendation was coordinated with OMB and the heads of departments and agencies for implementation by fiscal year 1974 or earlier to the extent practicable.

The basic program objectives continue to be:

To determine what biological effects radio frequency radiations cause under different conditions of exposure. For example, what are the effects of various frequencies, waveforms, energy levels, electric and magnetic field components, and exposure durations, and what is the possible influence of such biological considerations as age, sex, and health?

To determine the health and biological significance of any effects and to evaluate risk, with reference to realistic exposure environments.

To establish a sound scientific basis for any remedial and/or control measures which appear needed.

And, of course, to ensure that U.S. safety criteria provide an adequate margin of safety.

Where do we stand today? In many ways this program represents a unique approach to interdepartmental responsibility. I would like to touch briefly on our views of some of its accomplishments, its current status, and its problems. Additional information is contained in four summary reports issued by OTP.

Let me emphasize first that the research program, to date, has identified no positive evidence of harmful effects to man at the levels of exposure normally encountered by the general population. No crisis has been found to exist; no cause for public alarm has been identified; no specific mechanisms of interaction other than heating have been demonstrated. We must, however, be absolutely sure that nothing has been overlooked and we recommend continued and accelerated pursuit of the necessary research.

Mr. Chairman, I am pleased to be able to tell you that there have been some real accomplishments since this Committee's hearings in 1973. We do not yet have all the answers, but we have laid a solid foundation for developing them—in terms of the research capabilities that have been developed, the advances in the research itself, and the establishment of mechanisms for coordinating and pursuing this research.

We have succeeded in creating an Executive Office focal point and central forum for Government activities related to the biological effects of radio frequency radiation. This coordinated effort has given the additional identity to individual agency activities of being part of a larger program. It has also stimulated communication and exchange of information and interaction among the responsible government entities.

Each agency has designated representatives who meet with the ERMAC and serve as members of an interdepartmental working group. These individuals are identifiable and knowledgeable points of contact for activities in this area within their own agencies as well as with other agencies and the private sector.

Relevant research has been identified at the work unit level and organized to facilitate analysis and coordination of research efforts. This information is exchanged and available to all agencies, including those not actively engaged in research. It serves as a basis for technical reviews and for individual agency program planning and possible collaboration or mutual support of work which may be beyond the available resources of a single agency.

This, of course, is still a developing field of scientific endeavor without a large number of trained and highly skilled practioners ready to undertake research. Moreover, it involves highly complex technical problems and requires multidisciplinary skills. Since this Committee's previous hearings, there has been a considerable increase in both the level of technical sophistication and the numbers of investigators active in this research. Nonetheless, there is still a need to attract new investigators from various disciplines into this field.

There has also been an increase in exposure facilities available to conduct research over the wide range of frequencies and waveforms of interest. These facilities, including associated equipment and animal holding capabilities, are costly and required a considerable portion of the available research dollars, particularly at the outset. However, there remains a need for additional investment in facilities, particularly for studies involving long-term continuous or near continuous exposures.

In the actual conduct of the research, substantial progress has also been made. Better instrumentation and techniques have been developed for determining radiation dose and for measuring electromagnetic fields. These advances are critical to our ability to associate biological responses with exposures and to permit the extrapolation of animal experiments to man.

I am not going to elaborate here on specific research or results since I believe you have had the opportunity to hear from some of the agencies and investigators actually carrying out the work. However, I would like to point out that non-ionizing EMR research is far more complex than ionizing radiation. There are difficulties in relating absorbed energy to the incident radiation or "exposure." It is even more difficult to determine the distribution of that energy within the body. The body has different properties than air. It consists of different layers and structures of complex geometries and differing electrical properties which affect the internal distribution of absorbed energy. Frequency is very important as the degree of energy penetration is a function of the frequency; also there are questions about frequency dependent effects and resonances. We must also consider the effects of continuous wave emitters, pulsed emitters, and various other modulations and frequency combinations.

In the course of this research, biological effects have been observed and reported in experiments with small laboratory animals at levels around and even below 10 mW/cm^2 (e.g., in the range of 1–20 mW/cm^2). These effects include changes in learned behavior or task performance, radiation perception, and apparent alterations in electrophysiological measurements of nervous system activity.

While reports of such biological changes evoke considerable interest because of the level of current safety standards, they do not necessarily imply hazards to man for many reasons. For example, differences in size, geometery and physiology between humans and laboratory animals with respect to frequency and power density and the nature of an effect are among many factors which need to be taken into consideration in assessing or interpreting this research. Nevertheless, systematic study must continue to be vigorously carried out to determine under what conditions any biological effects occur and what their significance is to man.

In assessing the impact of this radiation on man one must develop a realistic picture of actual exposure environments and the populations which are involved. The EPA, DOD and other agencies have been conducting programs in this regard. While their work is still in progress, and actual measured data is somewhat limited, it appears that radiation levels in most environments normally encountered by the general public are well below 10 mW/cm^2, although levels of a few milliwatts/cm^2 do occur in some occupational situations. In fact, the EPA has estimated that approximately 99% of the general population is not normally exposed to levels exceeding 1 microwatt/cm^2 (which is 10,000 times less than 10 mW/cm^2).

Further hallmarks of a maturing effort include an increase in research in areas which have evolved out of EMR research itself and more studies to replicate observations. Studies are now being conducted with longer radiation exposures, although we need more work with still longer exposure periods. Also, the United States and U.S.S.R. have recently established an agreement to conduct collaborative research in the microwave area.

Our experience over the past few years has also made it possible for us to identify some of the problems and deficiencies in this effort. In our opinion, the major problem is that non-ionizing radiation research requires greater priority. Sufficient and stable funding is needed to attract new investigators, to develop exposure facilities and instrumentation, and to permit timely follow-up of project findings, experiments with long-term exposures, and studies of people who encounter non-ionizing radiation in occupational situations. Current funding is approximately $9 million per year. HEW, EPA and DOD account for approximately 90 percent of these funds.

Let me illustrate some of the problems:

EMR research has had to compete for resources within each agency against many other priorities, some with greater agency or public interest priority.

Research requiring relatively large and stable funding, such as experiments within long-term chronic exposures and large epidemiological studies, is beyond the particular resources of any individual agency for non-ionizing radiation research.

Certain types of research, for example, basic research, are not being funded at a high enough level because of the mission orientations of some of the agencies.

We are all aware of the increased attention and apprehension over the question of the safety of microwaves and other non-ionizing EMR. However, it is important to maintain a proper perspective.

Undertaking a research program in itself can imply that a hazard is either known or suspected. The development of a research effort means more investigators, scientific publications and public presentations, involvement of professional groups, and, hence, greater visibility. This visibility has led to more publicity in the popular press. However, because of the complexity of the topic, information is sometimes limited, out of context, and, as a result, difficult to interpret.

Even with all of the available information, interpretation of research results and their significance for man is complicated. Consideration must be given to such things as: the number of observations of a phenomenon; whether a finding can be repeated in the same or another laboratory; how findings in various laboratory animals can be related to man; and, whether an observed change or effect, in fact, constitutes a hazard. One must also distinguish preliminary findings from results of completed research and avoid drawing conclusions based on work still in progress.

The apparent differences in Eastern and Western research and safety standards also contribute to confusion. While we do not know the precise reasons, these differences may, to some extent, be due to different approaches to the development of standards and the definition of a "hazard." We hope that our recently increased contacts and cooperative research with Soviet scientists will help to resolve some of these apparent differences.

Finally, the use of the term "low-level" has created misunderstandings. It has often been indiscriminately applied to levels from fractions of a microwave/cm^2 to 10 mW/cm^2 and above (a range of more than 10,000). Levels of a few microwatt/cm are very high levels in communications or interference terms.

In summary, research to date has not demonstrated that any hazard to the general population exists. However, many questions remain unanswered, including some raised by the research we have conducted to date. Resolutions to these questions and experience gained make it possible to identify outstanding research needs and priorities. These are:

experiments to investigate effects of long-term, relatively low-level exposure;

studies of people exposed in specific occupations or special environmental circumstances;

increased investment in basic research, including investigations of mechanisms of biological interaction;

additional development and refinement of techniques and field measurement capabilities for determining radiation dose, for measuring internal energy fields and energy distribution and for interpreting laboratory findings to man.

Our goal should be a productive effort which continues to make effective use of the capabilities already developed by the agencies and makes it possible for them to meet the research objectives of this program.

In conclusion, I believe that a continued vigorous program of research based on long-term stable funding is necessary to develop a sound scientific basis for evaluating any possible biological effects from non-ionizing radiation, particularly at a time when use of the radio frequency spectrum is growing so rapidly. Further, I feel it is important that we assure that any regulatory or control measures be based on both demonstrated need and sound scientific judgment so that we can be sure that we have best served the total public interest.

[The following information was subsequently received for the record:]

OFFICE OF TELECOMMUNICATIONS POLICY,
EXECUTIVE OFFICE OF THE PRESIDENT,
Washington, D.C., October 20, 1977.

Hon. WARREN G. MAGNUSON,
Chairman, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: It was a pleasure to have the opportunity to testify before your Committee on the mater of nonionizing electromagnetic radiation effects. This is an important area which can have far reaching impact on our society. Continuing efforts to coordinate and ensure adequate support for responsible action—research, assessment, and regulatory—by the Federal Government are essential if we are to resolve the complex scientific questions and issues in this area in the public interest.

Responses to the specific questions in your letter of August 15 are contained in Enclosure 1.

We appreciate the opportunity to contribute to your review and your interest and support of work in this important area. We will be happy to provide any additional information you may require.

Sincerely,

WILLIAM J. THALER,
Acting Director.

Enclosure.

The following are responses to the specific questions posed in your letter:

Question. When will the ERMAC's review of the first five year plan be completed?

Answer. It is currently anticipated that the ERMAC's updated and revised program recommendations/guidelines will be completed by January 1978.

Question. How many agencies currently divide the $9 million available for research?

Answer. The estimated Federal expenditure is comprised of the independently funded efforts of 9 Departments/Agencies. (This does not separately count the 3 components of HEW and DOD, as shown below.) As can be seen DOD, HEW and EPA account for somewhat more than 90 percent of the funds and effort. Dollar figures should be viewed as approximate because of the differing fiscal/budgetary procedures of the various entities particularly for inhouse efforts—e.g., some agencies include all manpower and associated overhead whereas others (such as DOD) are "program dollars" only and do not include costs of military personnel, etc. (The National Cancer Institute and NASA/ERDA which have some relevant research, and OTP/OT are not included below).

FUNDING IN PERCENT

Department/agency	Fiscal year—		
	1976 plus transition quarter	1977	1978[1]
DOD	60.4	63.4	66.4
Army	10.2	9.8	9.6
Navy	39.2	40.4	40.5
Air Force	11.0	13.2	16.3
HEW	20.9	18.0	16.6
BRH	15.1	12.3	9.2
NIEHS	4.5	4.8	3.5
NIOSH	1.3	.9	3.9
EPA	13.0	14.1	11.3
NBS	1.6	1.8	1.7
NSF	2.8	1.2	2.1
FCC			
FAA			.2
VA	.9	1.1	1.0
CIA	.3	.3	.3
Amount (millions)	$9.2	$8.5	[1]$9.3

[1] Estimate.

Question. The electromagnetic radiation emanating from man-made sources has increased phenomenally since World War II. In 1973, your office estimated that U.S. government depreciated capital investment in communications and electronics exceeded $50 billion. What do you estimate current investment figures are?

Answer. The current (1977) estimated U.S. Government depreciated capital investment in electronics is $67 billion. This is an increase of $6 billion from the 1973 estimates. It can be expected that the incremental non-depreciated estimates of U.S. government electronics investment will range from $14.8 billion in 1977 to $19.5 billion in 1986, (ten year forecast using constant 1978 dollars). Of this yearly increase, all but about $2 billion/year is for DOD investment. The estimated U.S. government depreciated capital investment in electronics by 1986 will be $99 billion.

The $50 billion figure was a 1973 estimate for that portion of the electronics investment which is radio spectrum dependent. The best overall estimate now available (through 1976) is $52.4 billion (U.S. government) and $54.7 billion (non-government). It is projected that the 1977 estimate for radio specturm dependent equipment (U.S. government) will be $55.2 billion. No 1977 estimate is readily available for non-government radio spectrum dependent equipment.

Question. Suppose we find that microwave radiation does cause deleterious effects. Are there any emerging technologies such as coaxial cable and fiber optics which could be substituted for our heavy dependence on microwave sources? Please describe in further detail.

Answer. According to the Environmental Protection Agency, the most prevalent source of general public exposure to radiowaves are the broadcast transmissions of television and FM stations. Technically it would be possible to eliminate this exposure by the use of coaxial cable (already begun on a small scale) or fiber optic cable for transmission of the broadcast signals. It has been often suggested that such a replacement, for reasons other than biological harm concerns, would be desirable. Coaxial and fiber optic systems could provide improved service to the public simply by their ability to provide more chanels for programming. Such closed transmission systems would improve, substantially, the quality of the signals in that topography, structures, and weather would have no effect on the signals. Although such replacement is technically feasible, it would be accompanied by intense economic, regulatory, and legislative problems, particularly with respect to sparsely populated areas where the per-household costs of replacing over-the-air broadcast service can be much higher than in metropolitan areas. Finally, the removal of on-the-air broadcasts would free the presently allocated spectrum to be used for services that cannot be linked by cables or fibers, e.g. communication to aircraft, spacecraft and ships and land vehicles.

It would be possible to replace other sources of microwave radiation, such microwave relay transmissions, by cable. Such transmissions, however, are even weaker than broadacst signals. It is difficult to imagine that such levels are harmful to the general public. Additionally relay systems require no obstruction in their path and so are highly directional with minimal radiation outside of the primary beam. Likewise a substantial part of the satellite communications now in use could be replaced by cables, fibers, or millimeter wave guide; for example, a satellite communication network from New York to San Francisco. The present use of satellites, between fixed terminals within the 48 states is dictated primarily by economic advantages. Other technologies which may ultimately play role are through-the-atmosphere optical communications and "Hertzian Cable."

As mentioned previously, a number of services cannot be transferred to cable or fiber systems simply because at least one end of the transmission path is moving. Such services include mobile communications, radar for radio location, and radio navigation systems. In urban applications, there are some emerging technologies that would allow mobile units to transmit over short distances to relays which would distribute the signals to more remote relays by cable or fiber means. Obviously such innovations would offer only a partially reduced environmental radiation but they would alleviate problems of radio interference. Any system which must radiate through the atmosphere can be optimized to lowest possible levels by the use of sophisticated modulation schemes and appropriate receivers. However this would involve considerable increases in complexity, initial costs and maintenance.

The need for alternative technologies and the extent of any such use would be influenced by what electromagnetic field exposure conditions—frequency, waveform, power density, time, etc.—might be found to be responsible for any harmful effects. For example, a finding that such effects occur only under certain conditions (of frequency, etc.) would affect any such considerations.

Question. You recommended experiments to investigate effects of long-term relatively low-level exposure and occupational studies. But in your discussion of problems relating to the research program on the bio-effects of electromagnetic radiation, you mentioned that research requiring relatively large and stable funding, such as the low-level chronic effects and large epidemiological studies, are beyond the particular resources of any individual agency. Would OTP choose one agency that would be particularly suitable for conducting these sorts of studies, and recommend that there be commensurate budget increases?

Answer. Experiments involving long-term, chronic exposures—particularly continuous or near-continuous exposures—and epidemiological studies of occupational or other special population groups are costly and beyond resources currently available in the individual agencies for radio frequency microwave research. In both cases there are various conditions and situations requiring extended investigations. Research should be carried out where the best capabilities exist for conducting and/or managing the particular study in question. Specific determinations should be made on the basis of matching agency mission and technical and management capability with the specific task required. Broad guidance should be provided by a national advisory group which includes a broad range of scientific expertise and opinion and recommends parameters and priorities for such studies taking into account, for example, significant frequency ranges, exposure conditions, and biological/physiological or health endpoints of concern.

Several agencies have capability to carry out large-scale experiments with long-term exposures—namely HEW, EPA and DOD. The mission/program orientations of various entities are a consideration, particularly in terms of frequency or electromagnetic conditions to be studied. For example, a study involving electromagnetic pulse (EMP) exposures would be more logically carried out by, and be of, greater interest to DOD than to BRH, EPA or NIEHS. These considerations apply to both in-house as well as intra-mural programs as there should be some logical association with the supporting agency's program interests and responsibilities. Collaborative efforts involving funding and/or expertise of more than one entity should also be considered where appropriate. In particular, there should be a buildup in non-defense non-regulatory agencies for such work.

Similarly, epidemiological studies would best be carried out by those Departments/Agencies with relevant responsibilities and capabilities for this type of research. HEW, EPA and DOD all have capabilities if they could be made available for this work. Several HEW components have expertise and experience with human studies in a wide variety of fields. NIOSH has a responsibility for occupational and employment related health and safety. Other HEW groups and EPA would be logical candidates for conducting health studies, particularly of general population groups. Consideration should be given to utilizing capabilities in groups (government and nongovernment) not necessarily now involved in microwave research but possessing needed epidemiology expertise such as the National Center for Health Statistics or, perhaps, the Center for Disease Control (CDC). DOD also has strong environmental and preventative medicine interests and capabilities as well as having some of the potential occupational populations of high interest. Cooperative efforts should also be considered, for example between agencies with field measurment and survey capabilities such as EPA and groups, such as the National Center for Health Statistics or CDC, to ensure availability of the full range of capabilities and skills required.

Question. During the course of your oral testimony you mentioned that ideally you would support expenditures from $18 to $27 million as opposed to $9 million now spent on research programs. Could you amplify this comment? In an ideal world, which agencies and research programs would you allocate the extra dollar amounts?

Answer. This rough estimate[1] 2–3 times present levels, was based on unlimited budget authority and took into account research desires, the extent of the research community, the state of development of the field, and the experience of the research program over the past few years. For example, as noted in our letter to Sens. Ford and Stevenson of June 10, 1977, and in testimony, additional resources would be helpful in studies involving long-term chronic exposures, additional studies of basic mechanisms of interaction between EMR fields and living systems, studies of occupational or other special population groups, and further development and refinement of dosimetry which is critical to interpreting results of animal experiments and their relevance to man (as well as timely followup of research findings). Specific determinations should be based on the capabilities of the agencies and the particular research. The ERMAC is considering the matter of program requirements in preparing their revised recommendations.

---

[1] A similar estimate is made by the Second Task Force for Research Planning in Environmental Health Science.

Question. In oral testimony, Ms. Healer offered as an explanation of the difference between the Soviet and the American exposure standards, that the two may fundamentally differ on the definition of hazards. Please provide amplification of this statement.

Answer. While we do not know the precise basis and rationale underlying the Soviet standards there are indications that, to some extent, differences may be due to different philosphies and approaches to the development of standards and interpretation of "effects" in terms of "hazards." In discussions with Soviet scientists they have expressed the view that deviations, be they increases or decreases, in any naturally occurring factor in the environment in which man evolved are anticipated to produce a change or "effect." This prior view is not generally shared by U.S. scientists. Our approach would be to see whether a particular circumstance does or does not have an effect.

Additionally, it is important to distinguish between a "change" or "effect" and a "hazard." A biological or physiological change or effect does not necessarily constitute a "hazard." Numerous examples in our daily lives can be cited. For instance, running up a flight of stairs, or other moderate exercise results in a host of physiological "changes" such as increased heart rate, circulatory and respiratory effects, etc. which are not considered hazards under normal circumstances. Soviet scientific publications and, more recently personal discussions, suggests that the Soviets may use *any* physiological changes, even transient and subjective symptoms, as a basis for establishing safety criteria some appropriate order of magnitude below the lowest level at which such phenomena are found to occur. We generally look for objective signs and pathology and base our determinations of what constitutes a "hazard" on such objective criteria as a point of departure for the establishment of safety standards or criteria. It should also be noted that there is some ambiguity in the realm of field measurements and dosimetry. Many of the early Soviet publications upon which their present standards are based are not explicit as to how the field intensities associated with a reported observation were determined. This lack of information has made it difficult to evaluate the validity of some of these reports.

From our own experience we know that measurement techniques and dosimetry were not well developed in earlier work in this country and that this led to misleading conclusions. Different measurement techniques and the specifications of exposures may account for some of the differences.

Recent contacts indicate that the Soviets are undertaking additional research to reassess their conclusions and the scientific basis for their safety standards.

In any event, it is hoped that recently increased East-West contact and collaborative research will provide further insight into Soviet observations and the differences in our standards.

Question. In the course of your oral testimony Senator Schmitt asked for possible research and biological effects of intense magnetic fields. You responded that you knew of one researcher at the University from which you came involved in this sort of research. Please provide the Committee with a summary of this study and any others that you may know of.

Answer. The study referred to has been published as "Evidence of Morphological and Physiological Transformation of Mammalian Cells by Strong Magnetic Fields," by G. I. Malinin, W. D. Gregory, et al. A copy is attached.[2] In this study mammalian cells in frozen culture to 4.2°K were exposed for 4–8 hours to 5000 Oersted. Growth inhibition was observed and morphologically distinct cells were propagated through several generations. It should be noted that a field of this magnitude is a highly unusual environment and would be expected to be found only in the interior of electromagnetic systems specifically designed to operate at high fields.

A source of additional references to magnetic field effects is *Biomagnetic Effects: A Consideration in Fusion Reactor Development*, D. Dennis Mahlum, Battelle Pacific Northwest Laboratories, Richland, Washington, for ERDA), Rept. No. BNWL–1973 UC–20, February 1976.

Senator STEVENSON. Our next witness is Charles Hardin, member and past chairman of the Conference of Radiation Control Program Directors and manager of the Kentucky radiation control program.

STATEMENT OF CHARLES HARDIN, MEMBER AND PAST CHAIRMAN, CONFERENCE OF RADIATION CONTROL PROGRAM DIRECTORS AND MANAGER, KENTUCKY RADIATION CONTROL PROGRAM

Mr. HARDIN. Thank you, Mr. Chairman.

Mr. Chairman, members of the committee, I am Charles M. Hardin, manager of the Kentucky radiation control program, Frankfort, Ky. I am representing the Conference of Radiation Control Program Directors, an organization whose membership is comprised of all directors of radiation control programs in the 50 States, certain territories and large municipal agencies.

This conference is pleased to have been asked to testify before this committee on the vital subject of radiation health and safety. Mr. Chairman, I have submitted detailed written testimony for the record. However, the written document is too lengthy to read, but I would like to highlight some of the key issues presented in that written testimony.

Senator STEVENSON. Thank you.

The full statement will be placed in the record.

Mr. HARDIN. To properly understand the concerns of the conference, and its role in relation to State radiation control programs, a brief history and description may be helpful.

The Conference on Radiation Control Program Directors was formed approximately 9 years ago to serve as a forum for the exchanging of radiation health and safety information, between State and Federal agencies, as well as between States themselves. The conference is primarily supported by three Federal agencies; the Food and Drug Administration, the Environmental Protection Agency, and the Nuclear Regulatory Commission. We are also participating in projects of the National Bureau of Standards. The conference has served as a coordinating point on radiation health matters with several other Federal agencies such as the Department of Labor, the Energy Research and Development Administration, the Department of Transportation, and others. Additionally, the conference has liaison with the American College of Radiology, the American Society of Radiologic Technologists, and the American Registry of Clinical Radiography Technologists.

The overall goal of the conference is to assure that the patient who is to receive radiation, either diagnostically or therapeutically, the worker in radiation, the consumer, and the general public at large, receives the lowest amount of radiation exposure consistent with the benefit derived from such exposure.

In keeping with this goal, and the policy of serving as a forum for the exchange of information, the conference establishes task forces to evaluate, discuss, and subsequently to recommend specific actions to resolve identified problems. These task forces have representative membership from both State and Federal agencies. They may also have representation from professional associations and industry. Although, I do not have sufficient copies for the entire committee, for the record, I would like to submit two examples of reports from these task forces. The first is "Task Force Report on Bonding & Perpetual Care of Nuclear Care of Nuclear Licensed Activities," the second is a draft of the "Task Force Report on Natural Radioactivity Contamination Problems."

These task forces not only meet throughout the year, but they present their report at the annual conference meeting so that the conference may review and consider any recommendations made by a task force. Proceedings of these annual meetings are published, and again, although I do not have sufficient copies for the entire committee, I would like to submit the published proceedings of our last eight annual meetings. These proceedings will identify the issues considered by the conference, and the actions taken to resolve identified problems.

Mr. Chairman, at this time I would like to share with the committee some of the basic facts on State government's involvement in radiation health and safety. State radiation control began to develop in the early 1950's. Early impetus began principally with Federal support in the areas of model legislation, grant funding, and training programs for the States. Most attention in early State activity was concentrated in the areas of X-ray use and occupational exposure. Almost concurrently, State interest developed in the control of radioactive materials. This interest was addressed by Congress in 1959, by amending the Atomic Energy Act, which allowed for State participation in the control of byproduct, source, and special nuclear materials. The amendment permitted State participation by becoming an "agreement State."

As of June 30, 1976, all but two States, Puerto Rico, and the District of Columbia had enabling acts for radiation protection regulations. Twenty-five States have signed agreements with the Nuclear Regulatory Commission under authority of the Atomic Energy Act, as amended. Also, as of June 30, 1976, 45 States, Puerto Rico and the District of Columbia had regulatory programs in medical/dental X-ray control, with 43 States, Puerto Rico and the District of Columbia having regulatory programs in industrial X-ray control. As of June 30, 1977, 12 States and Puerto Rico had enabling legislation for the credentialing of the user of X-rays. Of this number 3 States and Puerto Rico have implemented credentialing programs, with 2 States scheduled to become operational in the immediate future. Eight other States have proposed legislation relative to use regulation.

In the area of nonionizing radiation, as of June 30, 1977, 21 States had specific statutes relating to the control of nonionizing sources.

In regard to resources expended at the State level for radiation control, for fiscal year 1975 over 523 man-year equivalence were employed.

During fiscal year 1975, over $11 million was expended by States in radiation protection activities.

One of the major radiation protection activities at the State level is the inspection of radiation sources for compliance with established health and safety regulations. For fiscal year 1975, over 25,000 dental and over 27,000 medical X-ray inspections were made. In addition, over 3,000 inspections were conducted for proper use of radioactive materials.

For more detailed analysis of State activities in radiation control, I would like to submit a copy of an FDA document "Report of State and Local Radiological Health Programs" for fiscal year 1975.

Senator STEVENSON. All of these submissions will be retained in our records.

Mr. HARDIN. Thank you.

A similar report for fiscal year 1976 should become available within the next few weeks. Mr. Chairman, the aforementioned facts and figures were to emphasize that States are involved in numerous and varied aspects of radiation health and safety.

At this time I would like to discuss the current radiation issues which the conference perceives that need addressing. These current issues, in their order of priority are:

1. The reduction of unnecessary radiation exposure from X-rays used in the healing arts. We believe that the main contributing factors to this unnecessary exposure are: (1) inadequate training in radiation protection by both the operators of X-ray sources and the nonradiologist practitioner; (2) the nonefficacious use of X-ray sources; (3) inadequate quality control programs in X-ray facilities, resulting in retakes of radiographs, and (4) improperly designed X-ray systems.

2. The reduction of unnecessary radiation exposure from radioactive material used in nuclear medicine. We believe the main contributing factors in this area are: (1) inadequate training in radiation protection; and (2) nonefficacious use of certain radioactive materials relative to other materials.

3. The reduction of unnecessary radiation exposures to the general population from various environmental sources, both ionizing and nonionizing. Examples of sources which we believe contribute to this environmental exposure are: (1) ionizing sources existing in nature, such as radioactive materials in phosphates; man-made and natural ionizing sources from the uranium fuel cycle, particularly uranium mill tailings and radioactive waste; and (2) nonionizing sources such as microwave and radio frequency transmissions.

4. The reduction of unnecessary radiation to the radiation worker, both from ionizing and nonionizing sources. Of particular concern for the worker is the use of both radioactive materials and X-rays in industrial radiography, and the use of the X-ray in medical fluoroscopy.

5. The reduction of unnecessary radiation exposure to the consumer public from both ionizing and nonionizing sources. Examples of ionizing sources in this area are the color television, which may emit ionizing radiation incidental to its primary use; and in the nonionizing area, microwave ovens. It would appear that industry is properly manufacturing these sources to meet FDA emission standards. How-

ever, there does appear to be a need for standards on microwave exposure limits for people, in addition to source emission standards.

6. The problem of laser radiation, a nonionizing source used in industry and educational institutions should not be overlooked. The conference feels this source represents a potential for unnecessary exposure to workers, students, teachers, and in some cases, the general public-at-large.

In addition to the six major radiation protection issues discussed above, the conference considers four specific programmatic problems should be brought to your attention.

1. Loss of State training from the Federal Government.—In the 1960's and early 1970's State radiation protection personnel received excellent training, either directly or through training grants from the Federal Government. Currently, with the exception of training supported by the Nuclear Regulatory Commission, only very limited Federal support for training of State personnel has been available. This lack of training has been especially noticed in the areas of X-ray and environmental protection.

2. Overlapping Federal jurisdiction in radiation protection activities.—There are 12 Federal agencies which the conference has identified with some responsibility or activity in radiation protection matters. From a State's viewpoint, this Federal picture appears to be very confusing as to which agency has responsibility for a given area in radiation protection. In many areas, there appears to be overlapping jurisdiction resulting in possible duplication of efforts, and in some cases, different standards relating to the same area. Two typical examples are: (1) The development of X-ray guides and/or standards in medical X-ray. Both the FDA and EPA appear to have active programs in this area; and (2) the development of emergency radiation plans. There are at least six Federal agencies involved in this area; specifically, the Nuclear Regulatory Commission, Environmental Protection Agency, Housing and Urban Development through the Federal Disaster Assistance Administration, General Services Administration through the Federal Preparedness Agency, Department of Health, Education, and Welfare through the Food and Drug Administration, and the Department of Defense through the Defense Preparedness Agency.

I understand NRC is the lead agency in this area, but we still have difficulty communicating with all agencies.

In light of this confusing Federal picture, the conference adopted a resolution in 1973, requesting Congress to consider consolidation of the various Federal agencies in radiation protection. A copy of this resolution is submitted for the record. The conference currently supports the general concept of consolidation of Federal activities in radiation protection, although we realize that one single agency may not be feasible. This would be especially difficult and not recommended, to combine regulatory agencies with nonregulatory agencies.

As an option, if consolidation is not feasible, we would recommend clear and concise "memorandums of understanding" between the various agencies, as to what their responsibilities are, and which is the "lead agency" for a given area, when legislation requires more than one agency to be involved.

3. Loss of direct Federal financial support to State radiation control programs.—During the early and middle 1960's, funding to States for radiation control was through Federal formula grants. These funds stopped in 1968, and as a result many State radiation control programs have financially suffered. These programs, which protect the citizen from biological effects that may be long term, and for which protection service is difficult to demonstrate immediate effectiveness, have had to compete with our health planning money and revenue sharing moneys. Some State radiation control programs have had very little growth or expanded activities since. I should comment, however, that other State radiation control programs have expanded their activities under State-generated funds.

4. Lack of uniform national criteria and/or standards.—There is an urgent need for national criteria or standards in certain radiation protection areas. Two specific areas are:

A. The regulation and control of radioactive materials not covered by the Atomic Energy Act. Specifically, naturally occurring and machine artificially produced radioactive materials (NARM). There is a significant gap in this area of control. The potential for unnecessary radiation exposure from NARM is as great, and with some materials such as radium, possibly greater than from materials which fall under the Atomic Energy Act. Federal legislation may be needed for the uniform control of this type radioactive material.

B. The siting, regulation, and perpetual care of "low-level" radioactive disposal facilities. Of the six commercial "low-level" sites, five are under State regulatory control, and all land on which these sites are located is either directly owned by States, or in the case of one site, owned by the Federal Government and leased to the State. At all sites, it appears that State government has the responsibility for the long-term perpetual care. There is need for national guidance and criteria of what constitutes acceptable sites for the disposal of "low-level" radioactive waste.

The above stated issues and programmatic problems are what the Conference of Radiation Control Program Directors perceive to need some attention or resolution for the proper radiation protection of our citizens. In some cases, congressional action may be needed for the proper resolution of the issues or problems.

Thank you very much for providing the conference an opportunity to express the views of the State radiation control programs on this vital subject.

Senator STEVENSON. Thank you, Mr. Hardin.

What are those low-level radioactive wastes to which you just referred?

Mr. HARDIN. Sir, would you repeat that?

Senator STEVENSON. What are those low-level radioactive wastes to which you just referred? Can you give us examples?

Mr. HARDIN. Currently, Mr. Chairman, there is only one definition of high-level waste, which is defined by the Nuclear Regulatory Commission. It relates to the liquids from fuel reprocessing. Materials that do not fall under that specific definition then fall under what are called low-level radioactive wastes.

Senator SCHMITT. Mr. Chairman, if you will yield, we have been involved with this a little bit in New Mexico with a possible siting problem. A large part of it is just the discards; that is, the gloves and the materials that were used in handling radioactive wastes.

Senator STEVENSON. That's what I am trying to find out. What are they?

Mr. HARDIN. Specifically they may be materials generated in nuclear medicine programs of hospitals, in which there are contaminated gloves, contaminated chemical wipes, that kind of material. There may be waste generated from the power industry. Again, contaminated clothing, tools, this kind of material used in the industry, as well as in the nuclear medicine field.

Senator STEVENSON. You say there are only six such sites in the country?

Mr. HARDIN. Six commercial low-level sites. I believe there are five low-level sites within the Federal Government area, within ERDA.

Senator STEVENSON. So those low-level wastes must be collected and then transported also?

Mr. HARDIN. That's correct, sir.

Senator STEVENSON. To these sites.

Is there a problem of control during the collection and transportation states also?

Mr. HARDIN. I do believe that risk could be in the transportation of these materials, and this is also one of the concerns of States, that these materials are carried across our borders to the sites in a safe manner. Thus far, there has been very little problem that has developed, although there have been a few accidents with materials.

Senator STEVENSON. Do the States take an interest in release of radioactivity from coal mines?

Mr. HARDIN. I am aware in relation to coal, Mr. Chairman, of some studies done of radioactivity directly in coal mines by the MESA, an agency of the Department of Interior. I have copies of those which indicated there is very little concern from a radioactive viewpoint to coal miners. As regard to the release of radioactivity to the environment from the burning of coal, we believe that is one area in which research needs to be done. I am not aware of any levels.

Senator STEVENSON. You are not aware of any levels. Do the States monitor radiation at coal-fired generating plants?

Mr. HARDIN. Not to my knowledge, sir.

Senator STEVENSON. Would you support legislation such as Senator Randolph has introduced, setting Federal minimum standards for the licensing of radiologic technologists?

Mr. HARDIN. Mr. Chairman, I fully concur with the concept that there is a need for the credentialing of X-ray operators. I fully concur with that. I think the majority of the States concur with that. I do believe, if I understand Senator Randolph's bill, would require Federal control. I believe what the States would support primarily is Federal guidance in this area, the developing of proper, uniform criteria and guidance, but that the administration of such credentialing should be at the State level.

Senator STEVENSON. I think that is what the bill does.

Let me ask, what if the State fails to meet the minimum Federal standards? Under the Randolph bill, would the Federal standards be applied to the States?

Ms. NELSON. Under Senator Randolph's bill the States would have 2 years after the Secretary promulgates minimum criteria to submit letters of intent to adopt the Federal standards or more stringent regulations. If the States did not submit such letters of intent, the Federal minimum standards would go into effect.

Mr. HARDIN. As far as the conference's position, they certainly do support the need for the credentialing of the X-ray user and in many cases, the credentialing of the nonradiological type of practitioner, as well.

Senator STEVENSON. It sounds as if they would support the Randolph approach, which establishes minimum Federal standards, but leaves the credentialing to the States.

Mr. HARDIN. Mr. Chairman, I am not that familiar with the exact wording of it. The concept I certainly would support. Exactly as to the words in the bill, I would have to read it carefully before I could respond to that.

Senator STEVENSON. What can be done to assure that physicians do not prescribe unnecessary X-ray exams?

Mr. HARDIN. Our recommendation there, the conference's recommendation would be—this is an area of medical practice and not a field of radiation protection in our area. The recommendation would be that studies be done by the medical profession. I understand the American College of Radiology has been studying the area of the efficacious use of X-rays. I would certainly recommend such studies be continued by the medical profession with guidelines from the medical profession as to what are efficacious uses of X-rays.

Senator STEVENSON. What more can be done to assure that equipment manufactured prior to the promulgation of the BRH standards is properly maintained and calibrated? I don't know why that question is confined to equipment manufactured before. I think equipment manufactured both before and after needs to be supervised. Based on prior testimony, we should maintain it up to standards.

Mr. HARDIN. The BRH recommendation is for the manufacture of new equipment. The States have programs to inspect and have regulations to control the use of the X-ray machines once they are out in the world being used.

Presently, I believe that most State programs have an adequate X-ray program to address the use of the old equipment, and several States are currently participating under contract with FDA to inspect the new manufactured machines that come out on the market. Possibly more States could be involved in the participation with FDA and the inspection of this X-ray equipment. If the budget of some States is expanded, they could possibly increase their surveillance of used and old equipment in the field.

Senator STEVENSON. You showed, for fiscal 1975, over 75,000 medical and 25,000 dental X-ray inspections were made. Can you give us some idea as to what percentage of all X-ray units were covered by those inspections?

Mr. HARDIN. Yes, sir. That information is in the document.

Senator STEVENSON. Can you give us an estimate now?

Mr. HARDIN. I believe if I recall reading the document—and I would have to get it confirmed—I believe an estimate would be something like 20 percent. Again, I would have to confirm that through the document.

Senator STEVENSON. Roughly how often are these machines inspected, and is there any effort to inspect the older equipment more frequently than the newer equipment?

Mr. HARDIN. That depends somewhat from State to State. I can express to you how it is done in Kentucky. Maybe it would be a little representative of that.

The priority of inspections are set based on the kinds of equipment that are being used, particularly the number of people that are being exposed by that particular X-ray source and the kinds of problems that we have found in the past with that particular kind of facility.

This turns out to indicate that something like a hospital will try to be inspected once every 2 years. Other sources of X-ray, like the gauges that are used in industry, of course, would have a priority very low, maybe once every 5 to 6 years.

Senator STEVENSON. What do your inspections reveal about the safety of this equipment?

Mr. HARDIN. I would say the inspections today, the findings of equipment today are much better than they were when we started back in 1962 or 1963. However, we are still finding there are certain items of noncompliance with our regulations, usually of a minor nature, however, not of anything major.

So, in general, the equipment viewpoint of that radiation and safety is in a reasonably good shape today.

Senator STEVENSON. You mean the equipment manufactured today?

Mr. HARDIN. Yes, sir. The manufacture of equipment—although I understand from the BRH testimony, there was found significant noncompliance. From the States' level of inspection, particularly of the old equipment, we have found that the industry, the professional people have upgraded their equipment substantially since 1962 and 1963.

Senator STEVENSON. The FDA estimates that between 30 and 50 percent of the new machines don't comply with the new standard.

Mr. HARDIN. Yes, sir. That was the reference of the testimony I was referring to of 30 percent of noncompliance.

Senator STEVENSON. Your experience is at variance with that? You were indicating that problems with new equipment now were minimal.

Mr. HARDIN. No, sir. I think possibly I misrepresented the two kinds of equipment. The States have been involved with the old equipment since the early 1960's. What I was speaking of, in which there has been substantial involvement, is that old type of equipment from the 1960's that is now being used and upgraded.

Let me give you an example. In the early years of inspection of X-ray equipment, we found very poor collimation of the beam, where the X-ray beam should cover only the area to produce diagnostic information to the patient, we may have found a machine in which the entire beam would cover the face and possibly other major parts of the body.

Today—that was in the early 1960's. Today, we are finding that that kind of equipment has generally been upgraded to where there are a very limited number of machines that have that problem.

Now, with respect to the newly manufactured equipment under the Federal performance standard, our experience, I suppose, would support the Food and Drug Administration, since we are participating with them under contract with several States. I have not tried to break the statistics out as to equipment manufactured under the performance standard versus the old equipment I was speaking of earlier.

Senator STEVENSON. Senator Schmitt?

Senator SCHMITT. What do you think would be the capacity of the States to administer Federal standards if they had regulations?

Mr. HARDIN. I believe the State programs would be able, and have performed well under the contract with the Food and Drug Administration in the inspection of this equipment and have provided them with very valuable, competently done information on the inspection of these equipments.

Senator SCHMITT. Do you think all States are willing to assume that kind of responsibility?

Mr. HARDIN. No, sir, I do not. I asked this question to some of the State representatives, specifically. Some of the answers about not wanting to participate primarily, I think, center around what they feel might be short-term Federal funds in which they would have people hired, buy equipment, get geared up and possibly later the funds would not be available in the next few years. That seems to be the overriding reason why some States were reluctant to sign a contract in this area.

Senator SCHMITT. They are reluctant to spend their own funds?

Mr. HARDIN. Some States have spent their own funds. They are spending their funds primarily in still addressing the older equipment. The equipment more frequently used in the field, sir.

Senator SCHMITT. Do you believe it is a political problem in the States? Do you think the people are unwilling to go to their legislators and ask for funds for this? Is there a lack of public perception?

Mr. HARDIN. You are speaking of the budget area, I suppose.

I think probably the more difficult problem is to demonstrate with the effects of radiation being long term and difficult to justify from a dynamic impact, it may be that the difficulty there is of getting the moneys through the legislative system, being able to demonstrate the real effectiveness of the program.

I would not say it's a political problem. It's more one of trying to identify and make the legislature aware of what the problem is.

Senator SCHMITT. It sounds like politics. If we had a Federal program which established standards and regulations based on those standards, would you think it important to know the economic health, and other impacts associated with the imposition of the regulation? Obviously it's going to cost the taxpayer something to have the regulation in place, both directly through taxes and indirectly through higher consumer costs, commodity costs, or service costs.

Also, it might cause a slowdown in the rate at which X-rays would be used for diagnostic purposes, partly through fear of violating regulations and partly through just the existence of the regulations and the paperwork that would certainly come with it. Do you think such an impact should be part of the issuance of various rules?

Mr. HARDIN. Yes, sir, I do.

Senator SCHMITT. Impact analyses, I mean.

Mr. HARDIN. The total field of radiation protection, including the development of regulations, should always be the evaluation of the benefit versus the risk or hazards associated with whatever one is doing, as it relates to the cost of the regulation, yes, sir.

There should be a cost-risk-benefit analysis.

Senator SCHMITT. You are under contract to the FDA for certain activities in this area. Did I understand that correctly?

Mr. HARDIN. Yes, sir, that's correct.

Senator SCHMITT. Do you feel there has been sufficient analysis of the effect of your activities in this area? Do you see any secondary effects? Are people more reluctant to use X-rays, for example, for diagnostic work?

Mr. HARDIN. I think we have seen over the years much more concern in regard to the safe use of these machines as a result of the regulations. As far as the reluctance of applying radiation to the human body, I cannot say that I have seen that reluctance.

Senator SCHMITT. Do you get involved at all in looking at research equipment which produces radiation, both ionizing and nonionizing radiation?

Mr. HARDIN. No, sir.

Senator SCHMITT. Do you think this is an area which should have regulation?

Mr. HARDIN. In the area of research? Yes, sir, I think there are areas that still need research.

Senator SCHMITT. No, no. Do you think research equipment that utilizes radiation should be subjected to the rules and regulations which apply to industrial, medical, and other uses?

Mr. HARDIN. Oh, yes, sir, very definitely. They represent a potential exposure of the operator of such equipment.

Senator SCHMITT. Do you inspect such equipment in Kentucky?

Mr. HARDIN. Yes, sir.

Senator SCHMITT. What do you find relative to other uses? Are researchers more careful? Less careful? Is it all about the same?

Mr. HARDIN. This would have to be a personal comment. From some of my personal experiences, I think in general I have seen that researchers possibly may be, with radiation sources, less careful in some areas.

Senator SCHMITT. They are the ones that are supposed to know the most about it; is that correct?

Mr. HARDIN. That's corect.

Senator SCHMITT. That is interesting.

In your discussion of naturally occurring radioactive material, I didn't quite understand what you were proposing. Are you proposing rules and regulations which might be established on a Federal level to restrict our access to these naturally occurring materials?

Mr. HARDIN. Yes, sir. I would say this is one area where you have a great deal of concern among the States.

The Atomic Energy Act specifically covers byproduct, source of special nuclear materials.

These are materials that exclude naturally occurring materials like radium and machine artificially produced materials. That means there is a group of materials existing on which there is very little uniform control. Most States which have signed agreements with the Nuclear Regulatory Commission require the same responsibilities of control for that kind of material as required for byproduct source, and special nuclear materials.

There are only 25 agreement States. That means there are other States that do not control or at least have limited control. About five States do have a rather strong, active licensing and enforcement program for these kind of materials specifically, but there are other States that have very limited activity on the control of this kind of material. So what I was mentioning in the testimony was there may be a need for Federal legislation—I don't know, but at least concern in uniform control of these materials that do not fall under the Atomic Energy Act, such as radium. Radium represents possibly as much of a potential unnecessary exposure to the population as any of the materials under the act.

Senator SCHMITT. You are thinking of radium which is in the commercial sector being used as a material, not necessarily radium which is in the environment?

Mr. HARDIN. That's correct. Such as in medical practice, for example.

Senator SCHMITT. There are environments in this country and elsewhere in the world where there is abnormally high natrual radiation. We call it abnormal because it is not normal, such as certain granite bodies in New Hampshire and certain water supplies in New Mexico come through uranium mines. You weren't proposing, necessarily, that human access to these areas be restricted?

Mr. HARDIN. No, sir. I was primarily talking about these kinds of natural materials once they have been brought from the surface and are being used for some specific, either medical or industrial application.

Senator SCHMITT. Many of them are already at the surface.

Mr. HARDIN. Yes.

Senator SCHMITT. You said there is a need for national guidance and criteria as to what constitutes acceptable sites for the disposal of low-level radioactive waste.

We are finding in New Mexico, since we are being examined by both ERDA and by a private company as a possible waste disposal site, that it probably doesn't make too much difference whether there are "acceptable sites," that the public perception of radioactive wastes is the dominant factor, and the demonstration of technical acceptability has very little relation to the psychological acceptability. Do you have any experience in that either in Kentucky or your association? Do you have any recommendations as to what the country should do to solve this problem?

The radioactive waste problem is here; it exists. However, we don't really have an acceptable solution yet because the people of this country are not psychologically willing to tolerate the disposal of that waste near them.

In New Mexico, we recently had a poll which showed three-quarters of the people were amenable to having a nuclear powerplant, but three-quarters of the people didn't want the waste stored in New Mexico. This kind of dichotomy is one we are somehow going to have to find a way around.

Do you have any comments to the committee?

Mr. HARDIN. I am very much in agreement with the comments that you just made. The technical and public perception of acceptability are two different things. Some members of the conference have had similar experiences. In Kentucky, yes, very definitely, we had similar experiences from that viewpoint.

As to the resolution of that problem of public and technical acceptance, it appears the only answer is more and better education of the—in layman's terms, of what the technical issues are that we are talking about so the public can have sufficient information to evaluate and determine what we are talking about.

I think it boils down to that, trying to do a better job of informing them in the kinds of terms they can understand what we are talking about.

Senator SCHMITT. You work at the grassroots level. Do you feel there is any significant effort in education in the area? You have to start at the very first grade in order to build an understanding of what radioactivity is, what its dangers are, what its benefits are, and what its myths are.

Mr. HARDIN. The main public educational effort I am aware of is the program of the Nuclear Regulatory Commission through their—I believe it's called atoms for peace program that has been out for many years as an attempt to inform the public. I think specifically——

Senator SCHMITT. Excuse me for interrupting. Do you see any effect of that program in Kentucky?

Mr. HARDIN. Yes. I think I have observed people that are knowledgeable about the basic information of radiation.

As far as it relates directly to waste disposal, that still appears to be a problem that needs more addressing.

Senator SCHMITT. Do you have any suggestions on this problem in time to implement a national energy program which contains some proportion of nuclear power?

We are using radioactive materials in a wide variety of other areas. Even this low level waste you referred to is unacceptable to local communities in many areas.

Do we have an insoluble problem for the next 30 or 50 years? Do you have some suggestions of what we can do both at the State level and the Federal level in order to solve those problems? Regulations probably won't solve them.

Mr. HARDIN. That is a very difficult question you pose of how to properly address the area of public acceptance relative to technical acceptance.

Again, Senator, the only answer that I can at all see is the matter of public information, informing the public with some intensive, concentrated efforts at both the Federal and State level to better inform the public as to what we are talking about.

Once we have done that, hopefully, then, there will be a meshing of the technical acceptability with public acceptance. I do not have a suggestion of the exact type program to inform them. I think that is the only answer.

Senator SCHMITT. Unfortunately, Mr. Hardin, the irrational sides of this question—and they are irrational on both sides—would tend to look at that effort as unacceptable. That's another part of our dilemma. You start educating people on radioactivity to the point where in one perspective they become knowledgeable enough to accept it and to be able to live with it, but that is unacceptable to those who think we should not be using nuclear power at all in this country.

I am not stating my own preference. I am saying that's the kind of dilemma everybody is faced with. It is probably more of a dilemma at the State level than it is in Washington where you are dealing with the problem. You have to deal both with the people concerned about radioactivity and people who have yet to fully understand what radioactivity is.

It is unfortunate radioactivity got its introduction to our society, to the general population, through a disastrous event; namely, the atomic bomb.

Most new technology has entered the society in a rather benign way and we have grown up with it. Nuclear technology came in with a bang—pardon the expression.

I think it is going to take people like yourself, people like the Congress, people all over this country to figure out how to handle this new technological problem.

I know the committee appreciates your attempts to work in this area. I hope you will continue to communicate to us individually or as a committee any ideas you may have on how we can get around it. I frankly have yet to see the solution.

Mr. HARDIN. I share your—I suppose the proper word would be frustration in this area. We share it also at the State level. We do have the concern that you expressed at being able to communicate the acceptability of the technical area to the public. We share that, sir.

Senator SCHMITT. It is a very immediate question. The administration has decided to move on this energy policy, if they can get the Congress to agree, into increased emphasis on the use of light-water nuclear reactors with an increased production of nuclear waste, at a time when we have no acceptable national means of disposal of that waste.

So it is a very immediate problem, and if it is going to take 30 or 50 years to get public acceptability for the disposal of nuclear waste, then I don't see how we can implement that particular policy.

I have no further questions.

Did you have a comment?

Mr. HARDIN. I would just like to make a comment with respect to the disposal of both high-level and low-level waste.

In my opinion, the technology appears to be there for high-level through the information that I have read. As relates to low-level, I believe that the disposal of low-level radioactive waste—into the Earth when it is properly managed is an acceptable situation.

Senator SCHMITT. Technically, I agree with you. Psychologically, we don't have acceptability.

Thank you, sir.

Thank you, Mr. Chairman.

Senator STEVENSON. Mr. Hardin, you mentioned that the natural sources of radiation include phosphates.

Could you be a little more specific? What kind of phosphates? Phosphates in fertilizer?

Mr. HARDIN. Yes, sir.

I believe there are a couple of States that are particularly having an environmental problem with the phosphate industry of fertilizer.

I think there are some reports by the Environmental Protection Agency regarding that.

Senator STEVENSON. Is this in the mining of the phosphates?

Mr. HARDIN. I believe, sir, it is the storing—and I am really not that familiar with the problem directly—I believe it is the storing of the materials, some of the residue.

Again, I am not that familiar. I would recommend looking at the Environmental Protection Agency publications on this matter.

Senator SCHMITT. Mr. Chairman, uranium and thorium are concentrated in phosphates by geologic processes. For the most part now, it is not being extracted from those phosphates as they are translated into fertilizer. Fertilizer using phosphates will have a higher level of radioactivity than normal.

Senator STEVENSON. OSHA testified that it performed 28 inspections last year of industrial and commercial radiation equipment.

Do the States inspect in these environments, commercial, industrial?

Mr. HARDIN. Yes, sir. Some of the States have become—have an agreement with the Department of Labor in carrying out the inspection of the worker and workplace as it relates to those materials that fall under the Atomic Energy Act.

Most radiation control programs inspect a facility not only for protection of the public, but for protection of the worker.

Specifically, let's look at, let's say, a medical facility using X-rays, in which our inspectors look not only at the proper collimation of the machine for exposure to the patient, but also the protection of the worker behind a protective barrier, whether or not that person is or is not wearing a proper monitoring device.

In addition to that, we look at the structural wall as to whether or not it is providing protection to the surrounding environment.

Senator STEVENSON. All such inspections are under contract from the Federal Government?

Mr. HARDIN. No, sir. There are only a few of these that are under contract with the OSHA program throughout the country. I am speaking specifically of the radiation control agency which I am representing.

I believe there are only two of those that have signed or are participating in some manner with the OSHA program. The other States are not. They are not under contract with OSHA nor are they under contract—well, those other States do participate with the Federal Government, with the FDA on some of their inspections.

As it relates to OSHA, I believe there are only two programs I represent that are participating in OSHA.

Senator STEVENSON. What I am getting at is do the States on their own do what OSHA is not doing, inspecting work places?

For example, the airports where equipment is used to scan baggage?

Mr. HARDIN. Yes, sir. The majority of States do perform on their own, regardless of the contract with OSHA—the governments I am representing do perform inspections of places such as airports in which the baggage inspection units are used, inspections of industry where radioactive devices are used, or radioactive materials are used, that are not under the Atomic Energy Act.

Senator STEVENSON. Do you have an idea as to how many such workplace inspections were conducted last year?

Mr. HARDIN. Again, I don't have the number available to me. I believe it is in this report that I submitted, sir.

Senator STEVENSON. One last question.

You have recommended reductions in exposure to radiation from microwaves and radar, radio frequencies. Others have testified that there is no evidence to prove harmful effects from such sources.

Are you suggesting that there is such evidence? Why are you recommending reduced exposure?

Mr. HARDIN. No, sir, I certainly have no evidence of any biological effects. My comment there related to the fact that I believe this is an area in which there should be research done to assure there is no risk involved.

Senator STEVENSON. Thank you, sir.

Senator SCHMITT. Could I ask one followup question?

With respect to the burning of coal and other fossil fuel sources, does Kentucky intend to look at the radition exposure levels in the State as a consequence of the use of coal? Do any States have such plans?

Mr. HARDIN. Senator, we have been concerned about this and thought about it on several different occasions, of the type of study that may need to be done.

I will say it is very low on our priorities, currently, of radiation protection activities.

We are aware of that as being a potential exposure source and possibly may include that in some of our environmental work in the future. It is not in our immediate plans.

Senator SCHMITT. Do you know of any other State's plans? For example, I don't know the particular levels in Kentucky, but the lignites of the Dakotas are extremely high in uranium concentration.

Mr. HARDIN. I am not aware of other States' plans.

Senator SCHMITT. This is not something your conference has discussed?

Mr. HARDIN. No, sir.

Senator SCHMITT. Do you expect to bring it up on the agenda in the near future?

Mr. HARDIN. This, again, would be a personal comment. I would think so. I would think sources of natural radioactivity would be brought up in the near future.

Senator SCHMITT. Thank you.

Senator STEVENSON. Thank you, sir.

[The documents referred to follow:]

TASK FORCE REPORT ON BONDING AND PERPETUAL CARE OF NUCLEAR LICENSED ACTIVITIES, APRIL 5, 1976

PREFACE

There is a need for States and other territorial governments to protect themselves from financial burdening should a licensed nuclear facility not be able to decommission its activities upon termination of a license. This has occurred in several States already, and several States have taken action to acquire the necessary legislation to allow the authorization of bonding requirements on certain licensees. While this may protect the States and other government agencies from enormous financial loss, it should be realized that this mode of protection is no substitute for a viable radiation protection program.

Bonding is anticipated for use in the immediate decommissioning of the facility covering approximately a one year period. The trust funds or escrow accounts should be provided for use in long-term or perpetual care and maintenance programs. Insurance would be an alternative for third party protection should that be deemed necessary. Other alternatives were considered; however, they were not generally considered viable.

It was the feeling of the Task Force members that such financial protection is not deemed necessary in the majority of cases, and should be reviewed by each State as to the applicability of its circumstances and those of its licensees.

The appendices of this report include suggested legislation for licensee bonding and perpetual care trust funds and, also, changes to the suggested State regulations allowing the authorization of such bonding and perpetual care funds.

INTRODUCTION

The Task Force on "Bonding and Perpetual Care of Licensed Nuclear Activities" was established by the Executive Committee of the National Conference of Radiation Control Program Directors during June, 1974, in joint sponsorship with the Nuclear Regulatory Commission (NRC) and the Environmental Protection Agency (EPA), to investigate options available to States to assure licensee financial responsibility in the event of default. This Task Force is an outgrowth and extension of previous deliberations on radioactive waste management, and bonding and perpetual care requirements for shallow land burial sites. Because similar considerations relating to bonding requirements exist for all types of nuclear activities, the specific charge of the Task Force was to examine, in detail, the requirements for establishing bonding and perpetual care programs for all types of licensed nuclear activities, and to report the findings of the Task Force as guidelines to assist States in program development. Therefore, this report addresses only the options of bonding and perpetual care and is an update of the January 20, 1975 Task Force Report. Other mechanisms of financial responsibility such as a national indemnity fund, taxation, insurance, and financial qualifications were considered.

A previous examination of the status of bonding programs as they relate to licensed nuclear activities (excluding waste burial licensees) indicates only one State, New York, had instituted such a program; however, several States expressed concern in this area and are interested in the results and recommendations of the Task Force. During 1975, North Carolina and Arkansas passed bonding legislation. This increasing concern is attributable primarily to the possibility that a State might have to assume the responsibility for restoring a site where a licensed nuclear activity was conducted, to a radiologically safe condition and/or maintaining the site in perpetuity. Commensurate with the technological advances and proliferation of the nuclear industry, the complexity of the restoration process of any licensed activity will, in all probability, require financial resources not available to the State. Since the public health and safety must not be compromised, it becomes necessary for the State to initiate actions to insure that its public responsibilities are met. While other concepts of assuring financial responsibility as a prerequisite for licensure are available and used, (e.g., the financial responsibility concept used by the NRC) it was concluded that the bonding and trust fund concept would satisfy many of the situations that an individual State may encounter and is, in the majority of cases, the method of choice.

The objective of the Task Force effort was to assemble into a single document the guidance necessary for State and Federal officials to develop bonding and perpetual care programs. Specific work topics were identified by the Task Force and in formulating the guidance, the approach taken was as follows:

To determine, in general classes, those licensed activities which may require consideration for bonding and/or perpetual care;

To identify the legislative authority necessary to establish bonding and perpetual care programs;

To develop monetary ranges of performance bonds and perpetual care trust funds; and

To identify administrative areas to be considered by the State in developing, implementing and maintaining bonding and perpetual care programs.

Ensuing portions of this report discuss each identified topic in detail, and in some cases, (e.g., legislative requirements) offer several alternatives and examples that may be considered. While attempting to suggest monetary ranges for performances bonds and trust funds, the Task Force found it difficult to etablish an exact cost estimate for any given class because of the variance of basic costs, as well as the differing restoration/maintenance requirements peculiar to the class. Wide monetary ranges are presented and are considered by the Task Force to be representative of minimum and maximum costs that may be encountered; however, each State must, using the identified parameters, evaluate the financial requirements of a given class by an individual cost analysis.

Finally, the Task Force has identified potential issues which should be considered prior to the adoption and implementation of any bonding or personal care program. Primarily, the issues relate to the following:

Licensing and regulatory jurisdiction over decommissioned facilities originally licensed by the NRC;

Difficulties that may be encountered by States if the NRC fails to adopt similar programs;

Reciprocal recognition of bonds between States and between States and the NRC;

Individual variability between States; and

Restricted availability of large dollar-amount bonds due to the collateral requirements.

Part IV, Recommendations, attempts to resolve these issues and also contains recommendations of the Task Force for a systematic approach to bonding/perpetual care programs.

The Western Interstate Nuclear Board is preparing a report of a similar nature on uranium mills and that report should provide additional information on this subject.

PART I PROBLEM DEFINITION

To investigate bonding and trust funds as a mechanism available to the State or Federal agency having regulatory jurisdiction over the activities of certain classes of users of radioactive materials to assure that sufficient funds will be available to decontaminate or decommission a licensed activity. The user classes identified are:

1. Major processors of radioactive material (not including special nuclear materials sufficient to form a critical mass);
2. Waste handling licensees;
3. Ore refineries—mills;
4. Former NRC licensed facilities which utilized special nuclear materials sufficient to form a critical mass; and
5. Other specific licensees.

The establishment of a financial responsibility program cannot be substituted for a sound, well-executed regulatory program, but employed only as a contingency in the event of licensee default. The Task Force has not endorsed the need for bonding of all licensees but if deemed necessary, the suggested legislation provides the mechanisms for such a program. Bonding and trust fund requirements should be instituted to assure the availability of money needed for the closing of nuclear activities and/or bonding the performance of a licensee relative to the protection of the public health and safety. Bonds would provide immediate, short-term financial resources to control and/or eliminate the radiological hazard; while trust funds would provide financial resources for long-term maintenance and surveillance costs if complete removal of the hazard is not accomplished.

For purposes of this report, the term "bond" means a contractual obligation in writing binding the obligor (licensee) to observe the provisions of the Laws, Rules and Regulations, Special Conditions, and Orders governing the issuance of the license, and in failure to follow such, to pay a sum of money to the obligee (agency) and permit the obligee or its designee to enter the property of the obligor for purposes of decontamination, with the stipulation to the effect that on performance of a certain condition (i.e., satisfactory decontamination by the obligor) the obligation shall be void. Used in this context, an acceptable bond may be any of the following:

1. A bond issued by a fidelity or surety company, if available;
2. A personal bond secured by collateral;
3. A "letter of credit" issued by a recognized financial institution; and
4. A cash bond posted by the licensee.

Bonds of this type are usually renewed on an annual basis and contain a short-term (30 days) cancellation clause by the surety which may require immediate action by the Agency.

In the context of this report, a "trust fund" means a legally established fund or aggregate of assets dedicated by the Trustor for the specified purpose of underwriting all costs of maintenance and surveillance of sites which pose radiation hazards or require continuing care; and which the beneficiary can spend under terms of the trust agreement only to effect the specified purposes.

I. MAJOR PROCESSORS

A major processor is considered to be a user processing, handling, or manufacturing radioactive materials exceeding Type A quantities as unsealed sources or material or exceeding four times Type B quantities as sealed sources, but does not include nuclear medicine programs, universities, radiographers or small industrial programs. Type A and B quantities are defined in 10 CFR 71.4.

A. NEED

A radioactive material user of this size usually will initially have an adequate financial base and can sustain significant expenses in decontaminating equipment or facilities and providing for the annual maintenance and surveillance of the site as required. In time, the company's financial resources tend to become limited if it cannot maintain its market position. In the event of a contaminating incident at the plant, the company may no longer have the financal resources to adequately correct the situation. The bond would provide funds to accomplish that task.

B. FACTORS TO CONSIDER IN SETTING THE AMOUNT OF A BOND

Setting the amount of the bond involves a complex evaluation of the licensee's activities being bonded. Factors to be considered are:

1. The amount, isotope, and chemical form of radioactive materials involved;
2. Facility structural factors, for example:
   - a. Types of ventilation;
   - b. Isolation capability;
   - c. Double containment and building design;
   - d. Above or below ground operations; and
   - e. Fencing or other access control;
3. Environmental factors, for example:
   - a. Water table;
   - b. Meteorology;
   - c. Migration rate (soil);
   - d. Surrounding water and land use; and
   - e. Access to facilities;
4. Costs of decontaminating rooms, equipment, etc.;
5. Costs of soil removal and disposal;
6. Costs of debris removal and disposal; and
7. Annual maintenance and monitoring costs.

C. ESTIMATED COST RANGE: $1,000,000 TO $5,000,000

After reviewing a proposed decommissioning of a major processor and discussing the factors to be considered in estimating restoration costs, the Task Force selected the estimated range as being representative of costs that may be incurred. Appendix A contains a summary of the estimate of a recent decommissioning of a major processor. The upper bound of the estimate includes complete removal.

II. WASTE HANDLING LICENSES

Waste handling licensees include organizations which hold radioactive wastes for later disposal and those which actually dispose of the wastes. Storage or holding of wastes generated solely by the storing organization would not be included. Those licensees which process the wastes prior to disposal should be considered major processors if the quantities of radioactive material which they are authorized to possess met the amounts described for that class.

A. NEED

The need for the bonding of waste handling license activities has been discussed in a previously developed statement by the National Conference of Radiation Control Program Directors and is Appendix B to this report. For those sites which serve as a temporary storage for wastes, the need as given for major processors above is appropriate. In addition, one should be aware that generally these companies do not have the equipment or mortgage base available should funds be needed.

B. FACTORS TO CONSIDER IN SETTING THE AMOUNT OF A BOND

Setting the amount of the bond for a waste burial site has been previously developed by the National Conference of Radiation Control Program Directors and is also included in Appendix B to this report. It should be stressed that the bond established for this type of licensee is for basically three things:

1. Burial of any wastes not buried by the operator;
2. Payment of any monies due the perpetual care fund; and
3. Preparation of the site for a new operator or for decommissioning.

Setting the amount of the bond for other waste handling licensees generally follows the factors considered for major processors. One should recognize that in many cases these licensees do nothing but handle Department of Transportation approved packages, thereby reducing the hazard potential.

C. ESTIMATED COST RANGE: $50,000 TO $500,000

Included in estimating these amounts are the decommissioning costs, funds due the perpetual care trust fund at the time of default or forfeiture and the maintenance and monitoring of the site for at least one year to permit possible site reactivation, if desirable. Perpetual care trust fund inclusion plays an important role in arriving at such a figure. A "point-of-no-return" would be identified at which time complete removal could no longer be economically considered in light of the health benefits involved.

III. ORE REFINERIES—MILLS

Ore refineries include all processors of a radioactive material ore. The product of this processing should not exceed the low specific activity definition given in 10 CFR 71.4(g). The waste product of the processing is usually radioactive "tails." Those processors handling radioactive materials concentrations above the low specific activity levels are considered major processors if the quantities possessed otherwise meet the amounts described for that class.

A. NEED

The need for bonding is best described by the need for continual control of the "tailing pond," or "tailing pile," or other retention system. The company operating the facility is subject to the same adverse financial conditions as described for major processors. In addition, the "tails" are likely to be considered disposed of and therefore may require extremely long term care.

B. FACTORS TO CONSIDER IN SETTING THE AMOUNT OF A BOND

The factors used in setting the amount of a bond for a major processor also apply to this class; however, certain modifying factors should be considered. These are:

1. Any contamination is low specific activity; therefore, decontamination of facilities and equipment is easier and cheaper.
2. The long term care requirements of the "tailing pond," "tailing pile" or other retention system, may require the establishment of a perpetual care fund. Appendix B discusses the establishment of a perpetual care fund and this Task Force recommends its consideration.

C. ESTIMATED COST RANGE: $500,000 TO $5,000,000

The cost range is for licensees with tailing piles and without need for relocation of the pile. A major consideration is the amount required for stabilization of the pile in connection with decommissioning of the facility. If a mill tailings pile, or other waste retention system, is not associated with the authorized use, appropriate downward adjustments of these figures would be required.

IV. FORMER NRC LICENSED FACILITIES

These facilities include all nuclear reactors, nuclear fuel reprocessing plants, uranium enrichment plats, and critical experimental facilities.

A. NEED

Fome NRC licensed facilities may be divided into two classes: (a) those with large inventories of mixed fission products and some transuranics; and (b) those with no transuranics and small inventories of mixed fission products. In all cases, long half-life materials are involved, and therefore the contamination must be removed or long term monitoring and perpetual care instituted. Otherwise, the need is the same as for a major processor.

B. FACTORS TO BE CONSIDERED IN SETTING THE AMOUNT OF A BOND

The factors to be considered in setting the amount of bond vary according to facility type. Generally, the considerations of a major processor apply, but additional factors should be taken into account for each type of production or utilization facility. These are:

1. Nuclear Reactors—The current NRC regulations provide for a detailed review of an applicant's financial resources to assure that the applicant can safety operate a nuclear power plant. Additionally, while in operation, the nuclear power plant represents a major asset to the operator; however, after the plant is decommissioned or shut down, it becomes a liability. It appears that the former nuclear reactor licensee will be under strong economic incentive to transfer title to another entity and thereby reduce the long term liability. It is recommended that any person holding an NRC "possession only" license for a decommissioned nuclear reactor be required, at the very least, to post a bond sufficient to provide a perpetual care fund covering the monitoring and maintenance costs for the liability.
2. Nuclear Fuel Reprocessing Plants—The considerations of this type of facility are the same as for a nuclear reactor.
3. Uranium Enrichment Plants—The considerations for this type of facility are the same as for major processors.
4. Critical Experiments Facilities—Those in low power range (<10 watts) have low fission product inventories and have the same considerations as major processors. Those in the high power range (>10 watts) should be considered, for bonding purposes, similar to nuclear reactors.

C. ESTIMATED COST RANGE: $50,000 TO $500,000

1. Nuclear Reactors—$50,000 to $500,000

   The estimated bonding costs for nuclear reactors depend on which of the four alternatives provided in the Regulatory Guide 1.86 "Termination of Operating Licenses for Nuclear Reactors" are used, the size of the reactor and the decontamination problems associated. Residual radiation levels on sites for unrestricted use should be as low as practicable but in any case far below those specified in Table 1 of the Guide. The estimated cost range does not include those decommissioning costs associated with termination of the NRC operating license but only includes those costs which may be incurred to provide annual maintenance.

The cost of decommissioning a two-reactor facility has been estimated at approximately $2,000,000, with a $100,000 annual maintenance cost. A complete removal of all radioactive material has been estimated at $75,000,000.

2. Other Former NRC Licensed Facilities—$50,000 to $500,000.
3. Critical Experimental Facilities—$10,000 to $100,000.

V. OTHER SPECIFIC LICENSES

A. NEED

Most of the users of radioactive material present a low potential for a major problem. For example, if a user of a gauge containing radioactive material declares bankruptcy, shipping the gauge to a licensed recipient is all that is required. Similarly, small research programs, nuclear medicine programs, industrial radiography, etc. each represent a fairly low cost decontamination problem. One should note that many programs start in this class and grow into another.

B. ESTIMATED COST RANGE: $1,000 (10,000) TO $500,000

Except for those licensees exempt or excluded from the recommended bonding requirements, an appropriate "across the board" (one amount for the entire class of licensees) application of a bond amount would be between $1,000 and $10,000 as a minimum. A normal maximum for this class could approximate $500,000. Complete removal of radioactive material is anticipated.

In providing guidance for perpetual care trust funds, the Task Force recommends that for only two cases—waste handling licensees and source material ore milling operations—should perpetual care funding be initially provided. Perpetual care funding may also be required for formerly AEC or NRC licensed facilities. All other sites would be expected to be decontaminated to a level as low as practicable to protect the public health and safety. This policy would preclude proliferation of perpetual sites throughout the nation. The interest on the amount required to be maintained in the trust fund should provide an annual amount equal to the anticipated costs of perpetual care. Anticipated costs of perpetual care for both waste handling facility and ore refinery sites would range between $50,000 to $250,000 per year. A trust fund principal of $3,000,000 will yield approximately $150,000 in interest annually, according to the 1974 National Conference Workshop No. 3 Report. The Report of Workshop No. 3 contains information as to the items of concern in providing perpetual care.

Bonding provides for the infrequent case in which a licensee is willing or unable to appropriately provide for decommissioning and the monies due to the perpetual care fund for the site. Perpetual care trust funds allow for the continuation of appropriate management of the site into the foreseeable future. It should be noted that bonding and perpetual care trust fund provisions do not provide for third party protection. While the Task Force was of the opinion that the licensing agency was under no obligation to require such insurance, it may be advisable to identify if licensees have provided for this matter.

PART II AUTHORITY

The purpose of this part is to discuss (1) the necessary legislative authority for requiring licensees to assure their financial responsibility through the posting of bonds and establishment of perpetual care trust funds; and (2) the requisites of performance bonds and trust funds. The Task Force is aware that some Agreement States have already determined that specified legislation to authorize bonding and trust funds of their licensees is not required, since their legal counsels have determined that the existing legislation establishing their agency provides sufficient authority for establishment of these requirements. However, the Task Force believes that most States will require an amendment to existing legislation in order to specifically grant the State the authority to require bonds and trust funds. Counsel in at least one State has stated that although existing law does not prohibit the imposition of bonds, the State would be in a stronger position if the legislation specifically granted the authority for the requirement of bonds.

Each State should investigate with its own legal counsel which of the two following approaches is appropriate for requiring bonds and establishing perpetual care funding within the State.

I. States where existing legislation is deemed adequate

For those States where legal counsel deems that the existing legislation provides sufficient statutory authority for the requirements of bonds and establishing perpetual care funding, the following criteria should be met:

A. The legislation should provide sufficient authority to establish the bonding and perpetual care fund requirement.

B. The authority to establish bonds should be broad enough to require bonds of adequate types and amounts.

C. The authority to establish perpetual care funding should be broad enough to cover the amounts needed for long term maintenance and surveillance of the site.

D. The legislation should specify where the proceeds of forfeited bonds are to be deposited and how they can be used.

E. The legislation should state any exclusions or exemptions from bonding and perpetual care requirements which may be deemed appropriate (e.g., State and local agencies) and should have a provision that additional exemptions by types of licensees may be provided by the State regulatory agency.

Where the State deems that the existing legislation is appropriate and meets the criteria as stated above, its rules and regulations implementing the statutory authority should be amended and, as a minimum, provide for the following:

A. A definition of what constitutes an acceptable bond (this may be defined within the state statute).

B. An effective date of the rule or regulation allowing at least a 90-day period for implementation.

C. A specific description of how the forfeited funds may be used; e.g., cleanup of contaminated facilities, etc.

D. A mechanism for administering the bonding and perpetual care requirements for existing State licenses.

E. A requirement that the bond be issued and in the possession of the State regulatory authority at the time the license is issued.

F. A requirement that the perpetual care fund be established prior to the time the license is issued.

G. A requirement for the provision of adequate bonding by range of dollar amount and a statement that all exemptions may be based on possession limit, form or other category deemed appropriate.

Appendix C "Proposed Changes to the Suggested State Regulations" contains an example of the language necessary to amend Section C.25 to include the above requirements.

II. States where it is deemed that amendment of existing statutes is necessary to authorize imposition of bonding and perpetual care funding requirements for licensees

All of the criteria for legislation and provisions that should be incorporated in the State rules and regulations, as discussed in the previous section, should be followed in conjunction with the enactment of amendment of existing State statutes to authorize bonding. Suggested language for such amendatory legislation is contained in Appendix D "Suggested Legislation for Licensee Bonding and Perpetual Care Trust Funds."

III. Other considerations

In addition to the legislative authority necessary to establish bonds and trust funds, each State regulatory agency should determine clearly what constitutes a legal bond or trust fund within the State. In the case of establishment of trust funds, the ownership of the land must be clearly defined. It is the Task Force's opinion that although bonds should be required of most specific licensees, trust funds for perpetual care are only necessary for waste handling licensees and ore refinery activities where tailings piles are generated. However, it was also considered that trust funds for perpetual care should probably be established for any former NRC licensed facility when it is decommissioned and when there is a likelihood that it will become a permanent disposal site as opposed to total dismantling of the facility or decontamination. Most States already have requirements for trust funds for waste handling sites, but these are all located on State owned property. In the case of ore refinery sites and former NRC licensed facilities, they are normally located on private property and thus the problem of ownership of the land must be clearly resolved.

PART III ADMINISTRATIVE

It should be recognized by the agency that implementation of a bonding/perpetual care program is no small undertaking either for the licensee or the agency. It is most important that the bond be in effect prior to issuance of the license, which is basic to the concept of any resultant legal procedure and is the only way adequate protection can be provided. Therefore, it should be a condition of issuing all new licenses that the bond in effect prior to issuance of the license. Assuming legislation or other legal authority authorizes the establishment of bonding/perpetual care programs, administrative procedures must be developed and provided to implement the program. Because bonds will frequently be a very significant cost item to some licensees, bonding requirements should be clearly delineated in the regulations governing the issuance of licenses by the agency.

Imposition of a bond upon all existing licensees should be accomplished by requiring all existing licensees to obtain a suitable bond as a condition of the license within a specified period of time or making a bond a condition of licensure at the time of renewal. In either case, adequate warning and necessary information as to the specific requirements of the bond should be provided to all licensees. Each licensee should be notified in writing as to the range of bond amount required. The time permitted should recognize the economic, legal, and administrative impact upon the licensee and the agency. Consideration should be made of the establishment of a priority system for administering the requirements of existing licensees. The letter should also provide information as to the availability of such bonds within the agency's jurisdictional area and should be clear of any implication of "conflict of interest."

It should be reemphasized that considerable staff time will be required of the Agency to implement this facet of its program with a lesser requirement for its maintenance. It is estimated that any agency having 500 existing licenses and which imposed a standard bond amount upon all such licenses, would require 1.5 to 2.0 man-years of technical staff for implementation and require 0.3 man-years effort for maintenance. It would also require 0.5 man-years clerical and secretarial staff time. In addition to staff time, all other costs for agencies such as legal services shoudl be considered if there is not a legal staff available to the agency.

Adequate written guidelines for staff use and implementation of the program should be provided. These should include procedures for the following:

1. Basic administrative processing of the bonding requirements in concert with existing administrative procedures of the agency and in accordance with a possible priority system.
2. Basic legal processing in accordance with laws governing such legal instruments.
3. Specific guidelines to be used in determining the amount of the bond required for each specific license.
4. Periodic review of bonding requirement as a normal license review and/or amendment procedure.
5. Periodic review at the expiration of the bond or licenses.
6. Provision for an adjustment of bond amount for inflation.
7. Implement a safe depository for the bonds.
8. Provision of written procedures to be implemented in the event of failure to perform adequately by the licensee requiring forfeiture of the bond.
9. Provision for the transfer of funds to the agency.
10. Provision for definition of proper use of bonding funds made available to the agency by forfeiture, including possible establishment of a trust fund for perpetual care.
11. Provision of written procedures for implementation of corrective action by the agency.
12. Provision of procedures for the establishment of a trust fund for perpetual care of the facility if need develops.

One method of assuring that an adequate period of binding is in efiect at all times may be to initially require a twelve month bond and further require that an additional six month premium be paid at the end of each six month period thereafter. This requirement would provide the agency with six months of lead time to take any necessary action against a licensee who refuses to obtain further bonding.

PART IV RECOMMENDATIONS

The Task Force has concluded that a financial responsibility review system, as a prerequisite for certain licensees to possess and use radioactive material, should be instituted at both the State and Federal level. Bonding and perpetual care trust funds can, to a limited extent, serve as an integral part of the system but caution should be exercised in relying totally on bonding programs because of the possible restricted availability of large dollar amount bonds. The Task Force found surety companies reluctant to issue assurance bonds in excess of $1,000,000 unless secured by 100 percent collateral; nevertheless, it is the position of the Task Force that bonding and perpetual care programs be considered as the principal option of the total financial responsibility assurance. Accordingly, the Task Force submits the following for consideration:

1. It is recommended that the Executive Committee of the Conference accept this report for presentation to the Conference and implementation of the recommendations as appropriate.
2. Further, other alternatives to bonding and perpetual care trust funds have been considered and are generally not viable. It is recommended that the Task Force be discontinued and that the Executive Committee establish a mechanism for periodically assessing the viability of programs instituted and the need for additional effort in this area.
3. Further, it is recommended that each State consider the adoption of a bonding and perpetual care trust fund program as a portion of the total financial responsibility review system.
4. Further, it is recommended that Appendices C and D of the report be submitted to Task Force No. 6 for inclusion into the Council of State Governments Suggested State Regulations and Legislation.
5. Further, it is recommended that the NRC consider the adoption of a similar financial responsibility review system for certain licensees that would include, as necessary, a bonding and perpetual care trust fund program.
6. Further, it is recommended that the Federal Government establish a policy providing for financial and technical assistance in taking remedial measures at the commercial radioactive waste disposal sites. (In concurrence with the GAO report "Improvements Needed in the Land Disposal of Radioactive Wastes—A Problem of Centuries," dated January 12, 1976.) Studies and remedial actions to be performed at ERDA radioactive waste disposal facilities should be accomplished with State radiological health program involvement.

APPENDIX A

SUMMARY OF THE COST ESTIMATE TO DECONTAMINATE THE AMERICAN NUCLEAR COMPANY

Excerpts from "A Study of Radioactive Contamination at the American Nuclear Company Plant," Oak Ridge National Laboratory, November 1, 1973

A facility with a "hot cell" operation and a storage well containing 50,000 curies of cobalt-60 and 18,000 curies of cesium-137 requires extensive decontamination. The facility has contamination throughout and has soil contamination due to waste treatment problems. The removal of the cobalt and cesium from storage, the welding shut of some doors, and decontaminating and securing the building to where the potential of public contamination is small would cost an estimated $145,000. To remove soil and decontaminate the building to the extent that unrestricted use of the property may be permitted was estimated to cost $1,000,000 to $2,000,000. One should note that the $145,000 would not cover the annual public cost to monitor or maintain the facility.

The estimated costs are as follows:

$90, 000	decontaminate "hot cell"
33, 000	decontaminate office
22, 000	excavate hottest earth
$145, 000	Total
(18, 000	additional for fence around 15 acres.)

APPENDIX B

1974 NATIONAL CONFERENCE ON RADIATION CONTROL WORKSHOP NO. 3 REPORT

What are the bonding and perpetual care requirements for waste burial sites?

Scope: This workshop is to consider the bonding and perpetual care requirements of State-licensed shallow land burial sites used for the disposal of radioactive wastes. Of particular concern is the problem of assuring sufficient funding to maintain, in perpetuity, the integrity and security of a waste burial site, including perhaps surveillance and monitoring. Similarly, the question of bonding to assure acceptable performance by the operator or to provide adequate operational funds in case of default by the operator needs to be explored.

PREFACE

As the scope of this workshop represents an extension of similar past considerations of the Conference's Task Force on Radioactive Waste Management, the following report should be appended to the April 24, 1974 report of that Task Force.

Workshop No. 3 recommends that the Executive Committee adopt the following as Conference recommendations:

"The State should assure that:

1. A performance bond is posted by the burial site operator payable to the State agency having the responsibility for closing and maintaining the site in the event of default or other inability of the operator to meet the requirements of the regulatory authority or contract obligations. Such performance bond should be adequate to cover the following costs:

   a. The decommissioning of the site so as to require minimum maintenance.

   b. The payment of any funds due the perpetual care trust fund at the time of default.

   c. The maintenance and monitoring of the site for at least one year to permit possible site reactivation, if desired.

   Generally, this performance bond should be between $50,000 and $500,000, depending on site characteristics.

2. A perpetual care trust fund is legally established which should draw interest adequate to pay the costs of monitoring and maintaining the decommissioned site. The perpetual care trust fund should be identified and limited to the monitoring, maintenance, and other perpetual care at the radioactive waste burial site. The estimated costs of monitoring and maintaining the decommissioned site should be re-evaluated periodically, but not exceeding five years and the contract with the operator renegotiated as needed.

   Items to be considered in determining the perpetual care trust funds are:

   a. Surveillance, including salaries, travel expenses, instrument maintenance, overhead, and well drilling.

   b. Maintenance of site, including labor, salaries, overhead, special equipment (evaporators, etc.), fence repair, and erosion control.

   c. Contingency fund, including potential protective actions to prevent unacceptable release of waste materials from the site, including land acquisition, and blocking procedures."

Generally, the annual interest from the perpetual care trust fund should be between $50,000 and $250,000 depending on site characteristics. $3,000,000 in a trust fund will yield approximately $150,000 in interest annually.

The perpetual care trust fund is the crux of the legal and financial matters to be considered. For the purposes of licensing, once radioactive material is buried it is no longer subject to the license possession limit. This is based on the concept that there is no intent to remove radioactive waste from the burial site and is the basis for the State assuming the responsibility for any costs of monitoring and maintaining the site after decommissioning. Prior to decommissioning, the license should be conditioned to require the operator to perform an adequate monitoring and maintenance program of the burial site, to both protect the public health and safety and to minimize future maintenance costs.

Once the radioactive wastes are buried in accordance with license conditions, any disinterment of the solid wastes resulting from changes in State or Federal regulations would be at State or Federal expense. Any disinterment of the solid wastes should only be performed under conditions specifically approved by the regulatory agency.

3. Nuclear Liability Insurance is posted in the amount of at least $1,000,000.

Regulatory authorities and other interested agencies should apply the above criteria to all future burial sites. Presently operating sites should meet the above criteria at the next license renewal and/or contract renewal.

Co-Chairmen: Aubrey Godwin, Alabama, Michael Christie, Idaho.

APPENDIX C

SUGGESTED CHANGES TO THE SUGGESTED STATE REGULATIONS

Sec. A.2 Definitions

* * *

(bb) "Major Processor" means a user processing, handling, or manufacturing radioactive materials exceeding Type A quantities as unsealed sources or material or exceeding four (4) times Type B quantitie as unsealed, sources, but does not include nuclear medicine programs, universities, industrial radiographers or small industrial programs. Type A and B quantities are defined in 10 CFR 71.4

(bc) "Waste Handling Licensees" means persons who hold radioactive wastes for disposal and/or those who actually dispose of radioactive wastes.

(bd) "Ore Refineries" means all processors of a radioactive material ore.

(be) "Former U.S. Atomic Energy Commission (EC) or U.S. Nuclear Regulatory Commission (NRC) Licensed Facilities" means nuclear reactors, or nuclear fuel reprocessing plants; or uranium enrichment plants, or critical mass experimental facilities where AEC or NRC licenses have been terminated.

Sec. C.25 General Requirements for the Issuance of Specific Licenses

* * *

(a) * * *

(b) * * *

(c) * * *

(d) * * *

(e) Bonding Requirements

(1) Pursuant to (cite provisions of the Act), and except as otherwise provided, a bond made payable to the (Director of the Agency) and in the amount specified in paragraph (e)(4) shall be posted to ensure the protection of the public health and safety in the event of abandonment, default, or other inability of the licensee to meet the requirements of the Act and these regulations.

(2) The bond required in paragraph (e)(1) shall be received by the (Agency) prior to issuance of a license. An acceptable bond is ———.

(3) Amendments to licenses in effect on (the effective date of this regulation) may be issued providing that the required bond is received by the (Agency) within 90 days after (the effective date of this paragraph (e)).

(4) The following specific licensees are required to post a bond within the range of amounts specified:

(i) Major Processors ($100,000–$5,000,000)

(ii) Waste Handling Licensees ($50,000–$500,000)

(iii) Ore Refineries—Mills, with associated trailings piles ($500,000–$5,000,000)

(iv) Formerly AEC or NRC Licensed Facilities ($50,000–$500,000)

(v) All others except persons exempt pursuant to paragraph (e)(5) (Minimum of $1,000–$10,000 to $500,000.) (A minimum bond shall be established if in the opinion of legal counsel it is necessary to meet State constitutional provisions on equality.)

(5) The following persons are exempt from the requirements of paragraph (e)(1) (A minimum bond shall be established if in the opinion of legal counsel it is necessary to meet State constitutional provisions on equality):

(i) All State, local, or other governmental agencies unless they fall in subparagraphs (e)(4)(ii) or (iii) above,

(ii) Persons authorized to possess no more than 1,000 times the quantity specified in Schedule B, Exempt Quantities, or combinations of radioactive materials listed therein as given in Note 1, Schedule B.

(iii) Hydrogen-3 contained as hydrogen gas in a sealed source,

(iv) Radioactive noble gases in sealed sources with no radioactive daughter product with half life greater than 30 days,

(v) Reserved (There may be others a State wishes to consider)

(vi) Reserved (There may be others a State wishes to consider).

(6) This paragraph (e) becomes effective on ——— (90 days after enactment of appropriate legislation or such time period as prescribed by the State Administrative Procedures Act).

(f) Perpetual Care Requirements

(1) Pursuant to (cite provisions of the Act), and as otherwise provided, a perpetual care trust fund shall be established prior to the issuance of a license.

(2) The following specific licensees are required to provide perpetual care funding. (Perpetual care funding may also be required for formerly ACE or NRC licensed facilities.)

(i) Waste Handling Licensees

(ii) Ore Refineries

Schedule B, Note 1

For purposes of Section C.25 (e) where there is involved a combination of isotopes, the limit for the combination should be derived as follows:

Determine the amount of each isotope possessed and 1,000 times the amount in Schedule B for each of those isotopes when not in combination. The sum of the ratios of those quantities may not exceed one (i.e., unity).

Example:

Amt. of Isotope A possessed

Example:

$$\frac{\text{Amount of isotope A possessed}}{1{,}000\times\text{schedule B quantity for isotope A}}+\frac{\text{Amount of isotope B possessed}}{1{,}000\times\text{schedule B quantity for isotope B}}\leq 1$$

Appendix D

SUGGESTED LEGISLATION FOR LICENSEE BONDING AND PERPETUAL CARE TRUST FUNDS

Section ———, Bonds

(a) The (Director of the Agency) or his duly authorized representative shall require the posting of a bond by licensees to provide funds in the event of abandonment, default, or other inability of the licensee to meet the requirements of the (Agency). The (Agency) is hereby authorized to establish bonding requirements by classes of licensee and by range of monetary amounts. In establishing such requirements, the (Agency) shall give consideration to the potential for contamination injury, cost of disposal, and reclamation of the property.

(b) All bonds forfeited shall be paid to the (Director of the Agency) for deposit in a special fund by the (State Treasury) called the (Radiation Reclamation Fund). All monies in such Fund are hereby appropriated and may be expended by (Director of the Agency) as necessary to assure the protection of the public health and safety. Monies in this fund shall not be used for normal operating expenses of the Agency.

(c) A bond deemed acceptable in (name of State) shall be a bond issued by a fidelity or surety company authorized to do business in (name of State), a personal bond secured by such collateral as the (Director of the Agency) deems satisfactory, cash bond, or a letter of credit. (Acceptable bonds may be spelled out in existing State laws and this provision should be consistent with those laws.)

(d) All State, local, or other governmental agencies, or subdivisions thereof shall be exempt from the requirements of this Section ———. The (Director of the Agency) is authorized to exempt classes of licensees from the requirements of this Section when a finding is made that such exemption will not result in a significant risk to the public health and safety. (If a State constitutional problem exists, Section C.25 (e) (5) must be revised accordingly.)

Section ———, Perpetual Care Trust Funds

(a) The (Director of the Agency) or his duly authorized representative shall require a licensee to deposit funds, on an (annual, semi-annual, quarterly) basis, in a trust fund when it is deemed there is a reasonable possibility that the licensed activity may eventually cease to operate although still containing, or have associated with the site at which the licensed activity was conducted, radioactive material which will require maintenance, surveillance or other care on a continuing and perpetual basis.

(b) In order to provide for the proper care and surveillance of sites subject to paragraph (a) of this Section, the State may acquire by gift or transfer from another government agency or private person, any and all lands, building, and grounds necessary to fulfill the purposes of this Section. Any such gift or transfer is subject to approval and acceptance by the State.

(c) The (Department) may by lease or license with any person provide for the operation of a site subject to this Section for the purpose of carrying out the provisions of this Act. Any lessee or licensee, including all State, local, or other governmental agencies or subdivisions thereof, operating under the provision of this paragraph (c) shall be subject to (Section ———, Bond).

(d) The funds required by paragraph (a) of this Section shall be established at such rate that interest on the sum of all funds reasonably anticipated as payable shall provide an annual amount equal to the anticipated reasonable costs necessary to maintain, monitor and otherwise supervise and care for the lands and facilities as required in the interest of public health and safety. In arriving at the rate of funds to be deposited, the (Department) shall consider the nature of the licensed material, size and type of activity, estimated future receipts and estimated future expenses of maintenance, monitoring, and supervision.

(e) All funds accrued as interest monies deposited in the perpetual care trust funds are hereby appropriated and may be expended by the Director to monitor and maintain the site as required to protect the public health and safety on a continuing and perpetual basis.

Recognizing the uncertainty of the existence of a person or corporation in perpetuity, and that ultimate responsibility to protect the public health and safety must be reposed in a solvent government, without regard to the existence of any particular agency or department thereof, all lands, buildings, and grounds acquired by the State under paragraph (b) of this Section shall be owned in fee simple absolute by the State and dedicated in perpetuity to the purposes stated in paragraph (b). All radioactive material received at such site and located therein at time of acquisition of ownership by the State becomes the property of the State.

(g) In the event a person, licensed by any governmental agency other than the State of (name of State), desires to transfer a site to the State for the purpose of administering or providing perpetual care, a lump sum deposit shall be made to a trust fund. The amount of such deposit shall be determined by the (Director of the Agency) taking into consideration the factors stated in paragraph (d) of this section.

Section ———.

(a) The provisions of this Act are severable and if any part of the Act is declared invalid or unconstitutional, such declaration shall not affect the validity of the part which remains.

(b) The Act is cumulative and is intended to supplement existing laws, and no part shall be construed to repeal any existing law specifically enacted for the protection of public health and safety.

(c) The provisions of this Act shall take effect 90 days after its passage and approval by the Governor of its otherwise becoming a law.

PREHEARING QUESTIONS AND RESPONSES OF THE CONFERENCE OF RADIATION CONTROL PROGRAM DIRECTORS

RESPONSE

Question 1. Please review your current programs and identify for the Committee the issues which you perceive are in need of resolution. This discussion may include those issues which appear to be of immediate consumer concern or those issues which are relevant to a clarification of federal agency responsibility. They may include your views as to needed revisions in existing legislation, initiation of research, education and training, state and federal cooperation, transportation, materials handling, disaster response, inspection or certification of devices and other similar issues.

Answer. To properly review the current programs of the Conference of Radiation Control Program Directors, and to identify the issues which need resolution, a brief description of the Conference may be helpful. The Conference of Radiation Control Program Directors (CRCPD) is an organization whose membership is comprised of all directors of radiologocal health programs in the fifty states, the territories and certain large municipal agencies. The Conference was formed approximately nine (9) years ago to serve as a mechanism for providing a more functional means of exchanging information between state and federal agencies, as well as between states themselves, in areas of mutual concern or interest.

The over-all goal of the Conference is to assure; that the patient who is to receive radiation, either diagnostically or therapeutically; the worker in radiation; the consumer; and the general public at-large receives the lowest amount of radiation exposure consistent with the benefit derived from such exposure.

In keeping with this goal and the policy of serving as a means of federal-state, state-to-state coordination when certain radiation problems warrant specific consideration, the Conference establishes task forces with respresentative membership from appropriate federal and state agencies. The purpose of the task forces are to evaluate, discuss and subsequently to develop resolutions to the identified problems. These task forces meet, as required, through the year to specifically address their assigned tasks, and then annually the total Conference meets to consider the task force recommendations of the proposed resolutions to the identified problem. The proceedings of these annual meetings are published.

Although I do not have sufficient copies for the entire Committee, I would like to submit to the Chairman, copies of these Proceedings for the last nine (9) annual meetings. These Proceedings will identify the issues considered at that time to be problems and the Conference's actions to address those problems.

The current radiation problems which we perceive that need resolution, in the order of their priority, as as follows:

I. The reduction of unnecessary radiation exposure from x-rays used in the healing arts profession. Unnecessary radiation exposure in this area can be caused by:

a. Inadequate training in radiation protection techniques and procedures, and in some cases inadequate training in the actual diagnostic and/or therapeutic procedures being performed. While this inadequate training applies primarily to the operators of the x-ray sources, in many cases to the non-radiologist practitioner supervising the operator is also in need of specific radiological training.

b. The non-efficacious use of x-ray sources by the prescribing practitioner. Studies have been published by the healing arts profession questioning certain x-ray exams or procedures as being unnecessary. Some examples of the exams or procedures questioned are: (1) exams for medical-legal protection of the practitioner, although not necessarily medically indicated; (2) routine pre-employment x-rays regardless of any pre-determined medical need; and (3) routine pre-emission of patients into hospitals.

c. Inadequate quality control programs within x-ray facilities to assure consistent, reproducible radiographs. This lack of quality control results in re-taking of the film, thereby essentially doubling the exposure to the patient.

d. Improperly designed x-ray systems.

II. The reduction of unnecessary radiation exposure from radioactive materials used in nuclear medicine. Unnecessary exposure in this area is caused by:

a. Some inadequately trained personnel, particularly those in the allied health profession.

b. Non-efficacious use of certain diagnostic radioactive elements vs. another radioactive element which provide basically the same diagnostic information, but with different amounts of radiation close to the patient and radiation worker.

III. The reduction of unnecessary radiation exposure to the general population from various environmental radiation sources. These include both ionizing and nonionizing radiation sources. Specifically, in the ionizing area:

a. Natural sources, such as, (1) natural radioactive materials in phosphates; and, (2) natural radioactivity in commercial and private caves, and (3) other sources of natural radioactivity.

b. Uranium fuel cycle sources, such as (1) mill tailings; (2) transportation accidents; and, (3) waste disposal.

Specifically, in the non-ionizing area:

a. Microwave sources, such as radar and microwave communication systems.

b. Possible radio frequency transmission sources, such as, television transmitting units.

IV. The reduction of unnecessary radiation exposure to the radiation worker from both ionizing and non-ionizing radiation sources.

In the ionizing area, specific interest in the unnecessary exposure from the use of radioactive materials and x-rays in industrial radiography, and the use of certain types of medical x-ray sources, such as fluoroscopes.

In the non-ionizing area, specific interest in the unnecessary exposure in the industrial use of microwave and laser systems.

V. The reduction of unnecessary radiation exposure to the consuming public from both ionizing and non-ionizing sources.

In the ionizing area, the products which are of concern are products which are not designed to emit radiation, but which do emit radiation incidental to their primary use. An example: the color television set. It appears that most products which do produce ionizing radiation incidental to their primary use are currently being manufactured to meet the standards of safety established by the Bureau of Radiological Health in FDA.

In the non-ionizing area, the microwave cooking oven is of most interest. Presently, the control of microwave exposure from these ovens are by emission rate standards from the specific sources, which is where such standards should be applied. However, it appears that there is a need for minimum acceptable exposure rates of people (general population) in addition to the source emission standards.

In addition to these problems relating specifically to radiation sources, the Conference would like to address other problem issues which affect state radiation control programs in their efforts to protect the citizens of their states from unnecessary radiation exposure.

I. Loss of State Training. There has been a significant loss of radiological training of state personnel from the Federal Government, with the exception of training provided to states by the Nuclear Regulatory Commission (NDC). The availability of training, either direct training by the Federal Government, or financial support of such training, in the areas of x-ray protection and radiation protection of the environment is not available, or if available, only to a very limited degree. In the 1960's such training was available, and many state radiation protection personnel received excellent training from various x-ray and environmental courses provided by the Federal Government. There are such courses available at some major teaching institutions, but the costs are rather substantial, especially when related to small training-related budgets at the state level. Additionally, the courses which were previously provided by the Federal Government were generally more oriented to the specific state governmental problems in controlling radiation than those courses available through the major teaching institutions. There is also one great advantage of such courses being provided by the Federal Government. Students, who are from various states, will learn techniques and procedures from the same source of training, and the application of these techniques and procedures should result in more uniformity than if the various state students obtained training at different institutions.

II. Overlapping Federal Jurisdiction in Radiation Protection Activities. It appears that there are both overlapping jurisdictions from Federal agencies to Federal agencies, and from Federal agencies to state agencies. To put these problems in perspective from a states viewpoint, listed below are the Federal agencies which we have identified which have some responsibility in the control of radiation:

(1) Food and Drug Administration: BRH: X-ray, Non-ionizing, manufacturing regulations and field compliance. Bureau of Drugs: Radiopharmaceuticals—manufacture. Bureau of Foods: Radiation in/on foods.

(2) Nuclear Regulatory Commission: Regulations for the use of radioactive materials known as By-product, Source, and Specific Nuclear Materials. (It should be noted that these types of materials exclude naturally occurring and machine artificially produced radioactive materials.)

(3) ERDA: Large in-house activity, internal regulations and inspection, "Emergency Assistance for radiation accidents," IRAP.

(4) National Bureau of Standards: Calibration of sources and instruments.

(5) Department of Agriculture: Radiation levels in cheese, butter, milk.

(6) Environmental Protection Agency: Establishing guidelines in radiation protection and monitoring of the environment for radioactive contamination.

(7) U.S. Department of Transportation: Extensive regulations on hazardous materials for vehicular transportation. Also under D.O.T. are:

a. Federal Aviation Administration: Part of D.O.T. covering air transport of radioactive materials. Extensive regulations (F.A.R. Pt. 103).

b. U.S. Coast Guard: Regulations on water transport of radioactive materials.

(8) Department of Defense: In-house responsibility for regulatory affairs; participates with states in emergency response if military radiation sources are involved in an accident.

(9) GSA: Emergency response planning.

(10) OSHA: Regulations on occupational exposures criteria. Strong compliance program.

(11) Federal Bureau of Investigation: Has responsibility for nuclear extortion threats assisted by local, state and other Federal agenices.

(12) U.S. Postal Department: Regulations on shipping radioactive material by mail.

Although the Conference has most contact with the FDA, NRC, and EPA, state programs in radiation protection will, at one time or another, work with or have contact with, one of the agencies listed above. Many of these agencies are charged by legislation to develop regulations, and the legislation or the regulations promulgated under the legislation put pre-emptive type clauses related to state regulation in the same area.

Although for national uniformity, these type pre-emptive clauses are understandable, they can create problems at the state level in proper compliance of all such pre-emptive clauses simultaneously. For example, as related to radiation protection, the following pre-emptive clauses appear in Federal legislation or Federal regulations:

(1) "Compatible with": Atomic Energy Act of 1954, as amended. Specifically, Section 274 of the Act.

(2) "Identical too": PL 90–602

(3) "As effective as": OSHA Act

In light of the many federal agencies having responsibility in radiation protection, there are areas of duplication, and in many cases, what appears from the states viewpoint, confusion at the federal level on matters relating to radiation protection. In recognition of this problem, the Conference adopted a Resolution in 1973, urging the Congress to take necessary legislative action to consolidate the various Federal responsibilities. A copy of this resolution is included with the attachment of resolutions discussed under answer two.

The Conference currently supports the concepts of the Resolution, although we now realize that one agency may not be feasible. The Conference does strongly support the need for consolidation of the many and varied activities in radiation protection at the federal level. If consolidation is not a viable option, the developments of interagency agreements which clearly identify the responsibilities of the various agencies may help.

As an example of how various agencies present a confused position to states, in the development of X-ray standards. It appears that both the FDA and EPA are developing standards which relate to the use of medical X-ray.

III. Loss of Direct Financial Support to Radiation Programs at the Federal Level. In the 1960's, funding to states from the federal government was available through formula grants, specifically identified for radiation protection activities. However, these funds for radiation protection activities were stopped in 1968, and since then the state radiation control programs have had to compete with other state programs for funds available through comprehensive health planning grants, and funds provided states through the federal revenue sharing program. This strong state program competition for available funds has resulted in a slow growth of available monies in radiological protection activities in some states.

Another problem which has impacted on the state radiation protection budgets is the necessity of setting artificial priorities in the expenditure of funds due to certain federal requirements. An example is the need to develop state emergency response plans for fixed nuclear facilities, such as nuclear power reactors. These type facilities are entirely regulated, from a radiological health and safety viewpoint, by the Nuclear Regulatory Commission. However, for such a facility to be licensed by the NRC, the operator must demonstrate proper planning for emergencies through coordination with state and local agencies. The Conference fully recognizes the need for this coordinated planning, but the development of such plans, which require many man-hours, may not be in line with estabilshed priorities of state budget expenditures for more crucial public health issues such as protection in the use of X-rays.

In addition to the need of emergency planning, these fixed facilities also result in the need for environmental monitoring at the state level. Again, the Conference believes that monitoring of such facilities should properly be the responsibility of the states but the cost for such monitoring has effected the expenditure of monies from the total state radiation protection budget.

IV. Lack of Uniform National Criteria: There is an urgent need for national criteria areas of radiation protection. Such criteria is not only needed for proper protection of the public, and worker, but needed for the uniform application of regulations throughout the country. Specifically, there is a need for national guidance and criteria in the following areas:

a. The regulation and use of radioactive materials not presently covered under the Atomic Energy Act. Specifically, radioactive materials which occur in nature or are produced artificially by machines. This is an area of radiation control which has a significant gap. The Atomic Energy Act provides for regulatory control of by-product, source and Special Nuclear Material by the Nuclear Regulatory Commission, or an "Agreement State." However, in most states which do not have an agreement under the Act, there is varied control of naturally occuring or artificially produced radioactive material. "Agreement states" in general provide the same type regulation for both types of radioactive materials. There are five non-agreement states; Illinois, New Jersey, Pennsylvania, Michigan and Virginia, which also provide licensing requirements for the use of naturally occurring and artificially produced materials. There may be the need for federal legislative action in this area so that there is uniform effective control for naturally occurring and artificially produced radioactive materials.

b. Uniform national criteria is strongly needed relative to the siting, regulation, and perpetual care of "low level" radioactive waste disposal facilities. There are six commercial sites now dedicated for the disposal of radioactive waste. However, there are no established national criteria or guidance for, "what is" and "what is not" acceptable siting, regulation, and perpetual care fee collection for the operation of such sites. It is my understanding that the NRC and EPA are working toward the development of such criteria and guidance, but that such guidance may still be several years away.

Question 2. Please discuss the resolutions which the Conference has developed within the last 7 years with respect to radiation health and safety. Please include a status report on these resolutions, the current additional recommendations on radiation health and safety which should be addressed either by Congress or the federal executive agencies.

Answer. The Conference has adopted 14 Resolutions since its establishment in 1968. Copies of these resolutions are shown on attachment I. Appended to these Resolutions is a summary of each Resolution.

The first Resolution of the 1971 Conference, and the Resolution of the 1974 Conference relate to the credentialing of persons administring diagnostic x-rays. The majority of the Conference membership continues to support the position that there is a need for programs to assure that only adequately trained and experienced persons administer diagnostic x-rays to patients, and that the most effective method to assure this training and experience is through a credentialing mechanism. It should be noted that this position represents a majority of the Conference, but there are specific states which do not concur with credentialing as a mechanism for assuring the adequacy of training, and have adopted policies relative to that position. In respect to the implementation of a credentialing program, a majority of the members of the Conference believe that implementation of credentialing will be most effective at the State level, but strongly support the development of guidelines and recommendations at the Federal level, so that there will be a uniform application of credentialing throughout the United States.

Currently, there are 9 states and Puerto Rico which have enabling legislation and 3 states which have Attorney General opinions indicating authority for legislation for the credentialing of persons administering diagnostic x-rays. Of the states which have enabling legislation 5 states and Puerto Rico either have ongoing licensing programs or will have licensing programs in the near future.

In respect to the 2nd Resolution at our 1971 Annual Meeting, the Conference continues to support the position as expressed in this Resolution. There are presently 30 states which license the use of Radium, and several states regulate Radium through a registration program, but with limited enforcement action.

The Conference continues to support the concerns as expressed in Resolution No. 3 of our 1971 Annual Meeting. Several states have provided training programs and curricula for dental assistants, and many state dental associations or boards have adopted requirements of training and radition safety for dental assistants.

In respect to Resolution No. 4 of our 1971 Annual Meeting, the Bureau of Radiological Health, FDA, has responded to our Resolution by the development of several different type training packages available both to the users of radiation and to state programs. The Bureau is to be complimented for their efforts in this area.

Although the Conference endorsed Resolution No. 5 of our 1971 Annual Meeting, the recommendations of this Resolution have not been adopted into the suggested state regulations. However, it is my understanding that a majority of states have independently included the recommendations of this Resolution to administrative procedures.

The Bureau of Radiological Health, FDA, does provide financial assistance to states, under contract, which desire to assist the Bureau in the inspection of newly manufactured diagnostic X-ray equipment and components manufactured under the Federal Performance Standard. Therefore, the Conference feels that the recommendations of this Resolution have been answered.

In respect to the recommendations as indicated in the 2nd Resolution of our 1972 Annual Meeting, we believe that efforts are being made to develop performance criteria and survey methodologies for photofluoroscopic machines through task forces working toward amendments to the suggested state regulations.

The position of the Conference relative to the Resolution of our 1973 Annual Meeting was addressed in Question 1.

The Resolution of our 1974 Annual Meeting was addressed under Answer No. 1 of this section.

Recommendations as expressed in the 1975 Resolution of the Conference is still supported by the members of the Conference. In respect to the current status of this Resolution, the problem of uranium mill tailings piles continues to be a problem and to my knowledge there has been no Federal financial support for any remedial measures in correcting the potential hazards from these mill tailings piles.

We believe the Nuclear Regulatory Commission has properly responded to our request as expressed in Resolution No. 1 of our 1976 Annual Meeting.

Likewise, we believe that the recommendations as expressed in Resolution No. 2 of our 1976 Conference have been properly addressed, since the technical assistance activities of the Environmental Protection Agency as expressed in this Resolution have been restored, and the states are currently being provided with the needed technical assistance.

We believe that the expressions of Resolution No. 1 under our August 1976 actions, will be properly addressed through task forces which have been formed to address the quality assurance issue, not only in the area of nuclear medicine, but in diagnostic x-ray and eventually therapeutic x-ray.

The Conference feels that our Resolution No. 2 of our August 1976 actions have been properly addressed by the Nuclear Regulatory Commission.

Question 3. Please set forth your reasons for the resolutions calling for clarification or centralization of federal radiation safety and health responsibilities and activities. Discuss problems of state and federal coordination with respect to transportation, licensing, inspection of radiation devices, etc.

Answer. The major reasons calling for clarification or centralization of radiation activities at the federal level were addressed in question No. 1. However, some further discussion of the specific problems of state and federal coordination is warranted. The transportation of radioactive material is generally regulated by the Department of Transportation, although certain special types of shipments of radioactive material come under regulations of the Nuclear Regulatory Commission. Although the regulations which have been adopted by the Department of Transportation and the Nuclear Regulatory Commission for the packaging and shipment of radioactive materials appears to be adequate, the major problem seems to be one of inspecting for compliance to these regulations. The Department of Transportation seems to have only a limited number of field staff, expertise in radiological health matters, to perform inspections of the radioactive material in transit. Many states conduct their own inspections of radioactive materials being transported throughout their states, and some currently have agreements with the U.S. Department of Transportation for a coordinated effort in the enforcement of safety standards. Although previously discussed under answer No. 1, as relates to state/federal coordination, it cannot be overemphasized that there appears to be a gap in the control of radioactive materials not falling within the jurisdiction of the Atomic Energy Act. Specifically, the control of naturally occurring and machine artificially produced radioactive materials needs immediate attention, and possible federal legislation, to assure that there is uniform control for the protection of the public health and safety.

In respect to the inspection of radiation devices, the state programs have the responsibility for the inspection of the use of the radiation producing machines while the responsibility for the inspection of radiation producing machines at the manufacturing point is within the Food and Drug Administration. The Conference strongly supports the position that the states should maintain the responsibility for the inspection of the use of radiation producing machines. The majority of the members of the Conference also support the need for the inspection of devices manufactured under the Federal X-ray Performance Standard, and several states have entered into a contract with FDA to perform these compliance inspections. Some states have indicated difficulty in participating under this contract, mainly due to the potential problem of establishing a program with federal financial assistance under the contract, with the potential at a later date of the funds not being available and, therefore, resulting in the hiring of personnel under the conditions of a short time basis. I believe that more states would be willing to sign contracts with the FDA to perform x-ray inspections for compliance of the x-ray performance standard, if there could be assured continuity from one year to the next of financial assistance from the FDA.

Question 4. Please provide the Committee with a background and history of the Conference and discussion of any relationships established with the Federal Government, and any programs undertaken by the Conference which deserve mention.

Answer. The Conference of Radiation Control Program Directors, Inc. is an organization comprised of directors of radiation control programs in all states, territories, District of Columbia and several large local control agencies. The Conference was established approximately nine (9) years ago as a mechanism of information exchange between state and Federal officials. Since formation, the Conference has shown a continued growth in terms of membership, expertise and areas of scientific/regulation concern. While initial interests of the Conference were concentrated in areas of x-ray machine operation, occupational radiation exposure and regulatory control of radioactive material users, the scope of conference interests has greatly expanded into facets of population radiation exposure which were not as evident as when the Conference began.

Since the Conference was built upon the need for public health and safety from hazards of radiation, expanded use, technology and complexity of radiation sources has created an increased potential for public harm. Because the Conference is simply a reflection of the concerns of its members, we are providing to the Chairman, copies of a "Report of State and Local Radiological Health Programs, Fiscal Year 1975." This report is published by HEW and summarizes the status of state programs.

In this report, the HEW reported a total state and local expenditure of nearly 12 million dollars. This level of spending also represented an increase of 15 percent over fiscal year 1974 levels. The Conference points out these figures as an indication of the degree of state and local concern to provide public protection in a time of shrinking state and local resources. To what extent local or state resources will continue to be provided is, however, a matter of serious concern.

The Conference began and continues to grow with support from Federal agencies. In fact, most state radiation programs actually started as a result of model legislation, grants and technical assistance provided by the Bureau of Radiological Health, HEW. Since that time, the involvement of Federal authorities and agencies has grown significantly as stated earlier in question one. Yet, Federal support in terms of training and grants has dropped dramatically.

The Conference itself is supported primarily by three Federal agencies; FDA/BRH, EPA and NRC. Through the Conference, individual states are offered direct opportunities to discuss and oftentimes, develop programs of shared interest and/or responsibility. The Conference provides to the Federal agencies, a mechanism of direct interchange of ideas, views and concepts on which Federal activities are often developed. Interest shown in the Conference by other Federal agencies tends to indicate the success that their unique state-Federal relationship is viewed by other agencies.

Since the primary Federal agencies have differing areas of jurisdiction responsibility or interest, the Conference's relationship with a particular agency is based upon the appropriate area of interest. While obviously, the Conference/Federal agency interest is cemented by common concern for radiation protection, for the American citizen, the level of individual agency involvement with the Conference is based upon the Federal jurisdiction and how it relates to state government. For example, the Bureau of Radiological Health concentrates with the Conference in areas of x-ray protection, the Nuclear Regulatory Commission in areas of radioactive materials regulation, and the Environmental Protection Agency (Office of Radiation Programs) in areas of environmental radiation and standards guidance. The Conference also works with the National Bureau of Standards on items of equipment standardization and measurement, the Department of Transportation in areas of radioactive materials transport and the Department of Labor in occupational regulation. The Conference also has maintained contact with the Energy Research and Development Administration (ERDA) in matters relating to radioactive waste management.

When matters and/or issues arise concerning a new or changing radiation problem, the identifying agency or state will bring up this problem to the Conference. If the problem is of an "information only" nature, a distribution of this information occurs within the appropriate channel. If the problem is one in which a short term solution is required, direct coordination between appropriate jurisdictions is attempted by the Conference. If, however, the problem is one in which trends must be identified, impacts measured and action program developed, the Conference will address it in a task force approach. The problem of increased natural radiation levels resulting from the mining and refinement of materials such as phosphate can be used as an example. At the Conference's 1974 held meeting, a workshop was held to look into the problem caused by high radiation levels from the phosphate industry. The state of Florida had identified this as a potential problem. Based upon the workshop's suggestion, the Conference formally appointed a task force to scope the problem and to identify needs for action. Five state representatives of the Conference, who were from states potentially having this problem, were assigned as members. In addition, appropriate Federal agency representation was included.

The task force held meetings at which they visited sites where this problem was acute and research methods of improving and/or suggesting plans of action for the states. In June, 1977, this task force issued a draft report. The report of this task force, as well as a report of a task force on Perpetual Care and Bonding will be transmitted to the Committee Chairman.

Over the years, numerous problems have been addressed by this Federal/state task force mechanism. During this past year alone, the following areas were considered; x-ray quality assurance, soil contamination limits, emergency response planning, personnel dosimetry, notification of radioactive shipments, public impact of nuclear medicine practice, credentialing, mammography, radioactive waste management and others.

CONFERENCE OF RADIATION CONTROL DIRECTORS

RESOLUTIONS SUMMARY

Third Annual Conference—1971

Resolution No. 1—A recognition by the Conference of the necessity for the credentialing of both x-ray operators and supervisors of operators, with recommendations of criteria for us in credentialing.

Resolution No. 2—A recognition of the specific hazards in handling Radium and Radon, with recommendations for states to undertake a Radium licensing program.

Resolution No. 3—A recognition for the need of training in radiation protection for dental assistants, with recommendations for state dental agencies to adopt rules and regulations requiring training and testing in radiation safety, and for state radiation protection programs to develop recommended training courses for such personnel.

Resolution No. 4—Recognition for the need of continuing education for all radiation users, with recommendations that the Bureau of Radiological Health (BRH, FDA) develop training courses to address the need.

Resolution No. 5—Resolution of five southern states, endorsed by the Conference, regarding the proper wearing of personnel monitoring devices during fluoroscopic procedures.

Fourth Annual Conference—1972

Resolution No. 1—Recognition of the need for Federal financial support to states which assist BRH in the inspection of x-ray equipment falling under the requirements of PL 90–602.

Resolution No. 2—Recommendation to HEW for clarification of an issued policy statement entitled "The Chest X-Ray as a Screening Procedure for Cardiopulmonary Disease," with a further recommendation that HEW, in cooperation with the Conference, develop performance criteria and survey methodologies for photofluoroscopic machines.

Fifth Annual Conference—1973

Resolution—Recognition of the need for consolidation of radiation protection activities at the Federal level, with recommendations to the Congress to take necessary legislative action for such consolidation.

Sixth Annual Conference—1974

Resolution—A second resolution of the Conference (1st being Resolution No. 1 at the 1971 Annual Meeting) recognizing the need for assuring the proper training and experience of persons administering diagnostic X-rays, with recommendations to Congress and State Legislatures for the adoption of legislation addressing this need.

Seventh Annual Conference—1975

Resolution—Recognition of the potential hazard of uranium mill tailings piles, with recommendations that the cost for remedial measures on the piles created prior to the implementation of the National Environmental Policy Act be supported financially by Federal funds.

Eighth Annual Conference—1976

Resolution No. 1—Recommendation to NRC to review and purge its regulations which are not in step with current radiation protection policy.

Resolution No. 2—Recognition of the loss of technical assistance to states from the Environmental Protection Agency, with a recommendation that the President and Congress make efforts to restore this loss of assistance to the states.

August 1976

Resolution No. 1—Recognition of the need for a quality control program in nuclear medicine scintigraphic instrumentation, with recommendations of performance parameters for such a quality control program.

Resolution No. 2—Recognition of the potential loss of records of disposal for radioactive materials, when such disposal occurs in many locations, with a recommendation to the Nuclear Regulatory Commission to amend their regulations on blanket authorization for certain types of soil disposal to be modeled after their incineration regulations.

RESOLUTIONS

THIRD ANNUAL CONFERENCE 1971

Resolution 1

Whereas X-rays and radioactive materials were discovered in the last century and both have been used for diagnostic and therapeutic purposes since their discovery;

Whereas possible hazards to patients and the general public from both of these radiation sources have been studied and the data published, the unnecessary exposures from X-rays generally are greater than the exposure from radioactive materials; and the unnecessary exposures from radioisotopes are currently controlled much more adequately than control of X-ray exposures;

Whereas the effort expended for control of exposure from X-rays has been less than the effort to control the proper use of radioactive materials;

Whereas the genetically significant dose from X-rays is increasing rapidly as is the total use of X-rays on humans;

Whereas curtailment of the genetically significant dose from exposure to unnecessary X-rays is relatively easy;

Whereas radiation can be considered an agent which pollutes or disturbs the human environment and the admistrator of E.P.A. stated, and it was published in the proceedings of the State and Territorials Health Officers Conference December 7–10, 1970, that "the Federal Government is one of the worst polluters in the whole country . . . will take the lead in cleaning its own house";

Whereas "the States are the primary enforcement arm in environmental control"; and

Whereas the control used prior to 1963 was on the equipment and not the user: Therefore be it

Resolved, That the Conference of Radiation Control Program Directors recognize the necessity for people control in the use of X-rays on humans and that this control be manifested or implemented by adopting some general regulations, guidelines, and above all qualification for all users of X-rays for medical and dental diagnostic and therapeutic purposes; and be it

Resolved further, That the radiation protection component of all user qualifications be the same for all category of users and that the attached document for technologists entitled "Minimum Hours Required for Approved Training Programs in the Indicated Categories", plus "Licentiates Training Hours for Limited Permit Operators" and "Licentiate Minimum Didactic Training Hours for Limited Permit Operators" plus the ASRT and ACR requirements for the registered X-ray user be accepted as guidelines for all X-ray users or supervisors of users; and be it

Resolved further, That X-ray users employed by the Federal Government not be exempted from these user qualifications; and be it

STATE OF CALIFORNIA, DEPARTMENT OF PUBLIC HEALTH, BUREAU OF RADIOLOGICAL HEALTH

[Minimum hours required for approved training programs in the indicated categories]

LICENTIATES OF THE HEALING ARTS

RECOMMENDED MINIMUM TRAINING HOURS FOR LIMITED PERMIT OPERATORS

Permit category	Minimum training hours		
	Didactic	Clinical	Total
Musculoskeletal system (excluding skull, including spine)	80	160	240
Skull (without contrast media)	66	80	146
Chest	62	40	102
Gastrointestinal (with contrast media)	84	160	244
Genitourinary (with contrast media)	68	80	148
Photofluorographic	62	40	102
Leg: knee and distal portion	62	40	102

RECOMMENDED MINIMUM DIDACTIC TRAINING HOURS FOR LIMITED PERMIT OPERATORS

Subiect	Permit category—Recommended minimum didactic training hours						
	Musculo	Skull	Chest	GI	GU	PF	Leg
Anatomy and physiology	6	4	4	8	6	4	4
Positioning	16	8	4	16	8	4	4
Radiographic technique	8	4	4	8	4	4	4
Film processing	8	8	8	8	8	8	8
Equipment operation and maintenance	2	2	2	4	2	2	2
Radiological physics and radiation protection	40	40	40	40	40	40	40
Total hours	80	66	62	84	68	62	62

Note: These recommendations have been prepared for the California State Bureau of Radiological Health by: Reynold F. Brown, M.D. and Bruce M. Burnett, M.S. Radiological Health Sciences Education Proiect Department of Radiology, University of California, San Francisco.

Resolved further, That user qualifications include standards of education, training, and experience for each category of X-ray user and the prescribed means for assuring that the established qualifications and standards are met, whether it be by certification, licensing or other recognized people control.

Resolution 2

Whereas, the training and qualifications of physicians, nurses, hospital aides and technicians in the safe handling of radium and radon is reflected in the number of radiation incidents and/or unnecessary exposures: Therefore be it now

Resolved, That all states undertake a radium licensing and regulatory radiation protection program which will assure the adequacy of hospital staff training in the safe utilization of radium and radon. Hospital staff that become involved with radium or radon treatments shall be knowledgeable in fundamentals of radiation safety, safe handling procedures, accountability, emergency procedures and physical radiation characteristics of radium and radon.

Resolution 3

Whereas, it is recognized that health delivery systems are in a crisis and that increasing demands for health services call for solutions which will make quality health services more readily accessible to the patient at a reasonable cost;

Whereas it is recognized that one solution in the provision of quality dental care is to assign expanded duties to dental auxiliaries such as dental assistants, thereby allowing the dentist to apply his time and skills to the provisions of those services where his professional training and judgment are most needed;

Whereas it is recognized that in certain states, the state dental practice act has been amended to authorize expanded duties for dental auxiliaries; and

Whereas it is recognized that dental assistants can be trained in the principles of radiation safety sufficient to enable them to make radiographic exposures of patients, in a safe and proper manner while under the direct supervision of the dentist: Now, therefore, be it

Resolved, That the Conference of Radiation Control Program Directors urge that State dental agencies, when so authorized by statute, adopt rules and regulations pertaining to the expanded duty for dental assistants of making radiographic exposures of patients, under the supervision of the dentist and after satisfactory completion of a radiation safety training course; and, be it

Resolved further, That the Conference urge that State regulatory agencies develop and implement an adequate program of radiation safety training courses which will be available to all dental assistants who will be authorized by rule or regultion to perform radiographic exposures upon patients under the supervision of a dentist.

Resolution 4

Whereas medical X-rays are the major sources of public exposure to man-made radiation; and

Whereas the medical diagnostic use of radiopharmaceuticals is rapidly increasing; and

Whereas the increasing use of all radiation sources is resulting in increased occupational and public radiation exposure; and

Whereas the Conference believes that continuing education and training is essential for all users in order to eliminate unnecessary radiation exposure; and

Whereas there is a great need for adequate continuing education and training for all users: Therefore, be it

Resolved, That the State radiation control programs should:

strongly encourage users of radiation sources to seek continued training in proper techniques and radiation protection,

actively promote and assist in the development of such training in hospitals, other educational institutions and societies, and

exchange information on such activities for the mutual benefit of all programs; and, be it further

Resolved, That the Bureau of Radiological Health should develop effective training material and courses of instruction for users, provide such material to the State programs, and actively assist the State program in their user training activities.

Resolution 5

The Southern States of Alabama, Florida, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee, hereby resolve:

(1) that consistent guidance be provided to fluoroscopists and bedside radiographers regarding the location of personnel monitoring devices worn during fluoroscopy and bedside radiography;

(2) that if only one personnel monitoring device is worn during fluoroscopy and bedside radiography, it should be worn outside the protective apron at the neck-line position;

(3) that the location where the personnel monitoring device is worn should be recorded as an integral part of a fluoroscopist's and bedside radiographer's personnel monitoring record;

(4) that the Conference of Radiation Control Program Directors should endorse this resolution and investigate the practicability of amending the Council of State Government's suggested State Regulation for control of radiation to provide for Item No. (3) above.

FOURTH ANNUAL CONFERENCE 1972

Resolution 1

Whereas the implementation and enforcement of the Federal performance standards for diagnostic x-ray equipment will require the active participation of State and local radiological health personnel in the inspection and surveys of new x-ray equipment covered by these standards according to Federal evaluation procedures;

Whereas such additional workload on existing State radiological health programs will require additional funding resources not available within the States; and

Whereas Public Law 90–602 in Section 360E authorized the Secretary of the Department of Health, Education, and Welfare to reimburse the State and local jurisdictions for enforcement services required by the Act: Be it

Resolved, That the National Conference on Radiation Control make it a matter of record, its concern that the State and local radiation control programs will not be able to embark on the additional inspection requirements imposed by the Federal standard without assurance that such necessarily expanded programs will be reimbursed on a basis to be negotiated with such individual jurisdictions.

Resolution 2

Whereas the Department of Health, Education, and Welfare issued on April 24, 1972 a policy statement entitled, "The Chest X-Ray as a Screening Procedure for Cardiopulmonary Disease" endorsed by the American College of Radiology, the American College of Chest Physicians, and the National Tuberculosis and Respiratory Disease Association; and

Whereas the Conference of Radiation Control Program Directors has reviewed this statement and attendant press releases and finds significant confusion in the interpretation of the following items:

1. The intended audience (medical community, public health agencies, x-ray machine users, or the general public);
2. The x-ray equipment included (photofluorographic, mobile portable, and conventional fixed radiographic);
3. The type of facilities included (mobile vans and stationary facilities such as clinics); and

Whereas State radiation control programs are directly affected by the interpretation of this policy statement: Be it hereby

Resolved, That the Department of Health, Education, and Welfare clarify this policy statement in the areas outlined above; and, be it further

Resolved, That the Department of Health, Education, and Welfare, in cooperation with the Conference of Radiation Control Program Directors, review the need to develop performance criteria and survey methodologies for photofluoroscopic machines.

FIFTH ANNUAL CONFERENCE 1973

Resolution

Whereas the responsibility for the protection of the public and worker from exposure to radiation has been significantly fragmented at the Federal level;

Whereas this fragmentation of responsibility is divided among the Atomic Energy Commission, the Food and Drug Administration, the Environmental Protection Agency, the Department of Transportation, the Department of Labor, the Office of Emergency Preparedness;

Whereas this fragmentation is further exhibited between regional offices and headquarters offices with certain of these Federal agencies;

Whereas this fragmentation results in duplication, inefficiency, contradictions, and complexities in communication: Therefore, be it

Resolved that the Conference of Radiation Control Program Directors, urge the Congress of the United States to consider this serious problem of fragmentation and take the necessary legislative action to consolidate the various Federal responsibilities relating to radiation protection of the public and worker within one agency.

SIXTH ANNUAL CONFERENCE 1974

Resolution

Whereas there is a recognized need for assuring that persons administering diagnostic x-ray be adequately trained and experienced to assure safe and efficacious use of x-ray equipment for the protection of the public health and maximum benefits to patients;

Whereas the licensure programs operating in the States of California, New Jersey, New York and Puerto Rico provide a means of assuring the adequacy of training and experience of those persons operating medical x-ray equipment; and

Whereas legislation for implementing or continuing such licensure programs is now under consideration in both the U.S. Congress and State legislatures of some 10 States: Therefore, be it

Revolved The Conference urges the U.S. Food and Drug Administration to that the Congress and the several State legislatures adopt such legislation as is presently before them to assure the continuation or implementation of programs for licensure of operators of medical diagnostic x-ray equipment; be it further

Resolved The Conference urges the U.S. Food and Drug Administration to adopt a public policy supporting such legislation and that the Food and Drug Administration actively assist States in drafting State legislation and organizing an effective implementation of present and future operator licensing legislation.

SEVENTH ANNUAL CONFERENCE 1975

Resolution

Whereas, Uranium mill tailings piles are a real or potential hazard to the public;

Whereas, the uranium tailings piles are the results of mining for uranium fuel;

Whereas, uranium is necessary for energy production and national security;

Whereas, the benefits of economical electric power from nuclear power facilities is accessible to all U.S. citizens; and

Whereas, the cost of elimination of the health hazard of uranium mining tailing is prohibitive in cost to those States where they exist: Therefore, be it

Resolved, that the Conference of Radiation Control Program Directors recommends that any remedial measures on piles created prior to the implementation of the National Environmental Policy Act be accomplished at total Federal expense, and that when any such remedial measures are taken, it should be with the approval of State and local government.

EIGHTH ANNUAL CONFERENCE 1976

Resolution 1

Whereas regulations are constantly under revision;

Whereas there is a tendency to perpetually add to regulations;

Whereas seldom is any authorization which no longer having beneficial use removed from regulations;

Whereas regulations must be continually justified to those being regulated and the general public; and

Whereas a specific license can be used for those exceptional situations where the use is justified on a case-by-case basis: Therefore, be it

Resolved that the Conference petition the NRC to review its current regulations and purge those portions of the regulations not in step with present day radiation protection philosophy.

Two examples of the need for review are the general license of source material to physicians and pharmacists, and the Exemption from Licensing of scandium-46 for well logging.

Resolution 2

Whereas the technical assistance activities of the Environmental Protection Agency, including analytical laboratory support and radiation monitoring has been of immeasurable help to radiation control programs of the States, thereby benefitting the public health of the nation; and

Whereas the Environmental Protection Agency has been directed to reduce or eliminate the provision of such a system to the States: Be it, therefore,

Resolved, That the President and Congress of the United States be made aware of the concern of the Directors of State radiation control programs in the loss of such technical assistance and that the President and Congress be encouraged to make every effort to restore and perhaps increase this important and necessary function of the Environmental Protection Agency as one means to insure the continued protection of the Nation's public health and safety through cooperative State/Federal radiation control programs.

AUGUST 1976

Resolution 1

Whereas the continuous improvement of nuclear medicine scintigraphic instrumentation will yield high quality diagnostic images;

Whereas such images are essential to the evaluation and clinical management of nuclear medicine patients;

Whereas it should be the goal of all nuclear medicine departments to maintain a high level of diagnostic accuracy in interpreting scintigraphic images; and

Whereas such accuracy can be achieved in part by insuring the standardization of the performance of scintigraphic imaging instrumentation: Be it

Resolved, That scintigraphic instrumentation used to collect nuclear imaging data shall be quality control tested each day of use for minimization of variability in the following performance parameters:

a. Uniformity—the ability to produce a uniform image of a uniform "flood" source.

b. Spatial distortion—the ability to image arrays of linear sources of radioactivity with a minimum of distortion.

c. Resolving power—the ability to produce and display images of an array of radioactive sources which shall be discernible as separate entities.

Resolution 2

Whereas disposal records, while invaluable for compliance inspections, leave a question of accuracy;

Whereas once material has been disposed of, there is a tendency to forget completely about its location and amount;

Whereas disposal records are not required to be kept indefinitely;

Whereas constantly land is being placed into other uses;

Whereas many states have adopted the model solid waste disposal act which prohibits certain disposals by burial;

Whereas state radiation regulations should not be in opposition to other regulations;

Whereas regulations should not promote action unbeneficial to man and his environment; and,

Whereas should an exemption be deemed desirable, specific license conditions can authorize such disposal by burial as appropriate to the situation: Be it

Resolved, That the Conference petition the NRC that the blanket authorization for disposal by burial in the soil found in 20 304 of 10 CFR Part 20 be amended in its entirety. It is recommended that amendment be modeled after the disposal by incineration statement in 20.305 of 10 CFR Part 20.

[The following information was subsequently received for the record.]

CONFERENCE OF RADIATION CONTROL PROGRAM DIRECTORS

WARREN G. MAGNUSON,
Chairman, Committee on Science, Commerce and Transportation, U.S. Senate, Russell Senate Office Building, Washington, D.C.

DEAR SENATOR MAGNUSON: Thank you for the opportunity to further clarify some of the statements made during my testimony of June 29, 1977, on behalf of the Conference of Radiation Control Program Directors. I also appreciate the extension of my response time to your letter of August 15, so that I could accumulate more information from the various states. After receiving your letter a questionnaire was sent to all state radiation control directors addressing the specific questions raised in your letter. In addition to this questionnaire to the various states, I have also discussed some of the issues raised with some of the Federal agencies involved. I hope that the following answers to your questions accurately reflect the general consensus of those states that respond to my questionnaire, and information which I was able to obtain from the various Federal agencies with whom I had contact.

I will answer your questions in the order that they were asked in your letter.

Question 1. Please describe in more detail for the Committee what you mean by "regulatory programs"?

Answer. A state regulatory program, as related to radiation control, can be described as a program administered by a state agency to protect the citizens of that state from unnecessary radiation exposure by the enforcement of regulations pertaining to the safe use of radiation sources. Prior to the adoption of such regulations, most states, if not all, must first obtain authority to develop and adopt such regulations from the state legislature. This authority is usually granted through some type of enabling legislation, although in some instances the legislation may be specific as to the type regulations which are to be adopted, and in some cases the legislation may contain specific requirements regarding health and safety. In most cases, either the legislation and/or the regulations promulgated under the legislation carries significant penalties for violation of the laws or the regulations, which range from fines up to $5000 or imprisonment not to exceed six months or both fined and imprisoned. To enforce the regulations the state programs conduct routine inspections for compliance. When violations are discovered during these inspections, depending upon the severity of the violation, regulatory actions are taken which range from a notice of violation with request to comply, up through the issuances of orders, suspensions, revocations of licenses, and the imposition of appropriate fines. Usually the regulations provide for confiscation of sources if there is an immediate danger to the health and safety of its citizens.

Question 2. What do most State regulations entail?

Answer. Most state radiation regulations follow the Suggested State Regulations which have been developed by the Conference of Radiation Control Programs Directors, the U.S. Nuclear Regulatory Commission, and the U.S. Food and Drug Administration. These regulations generally conform to the recommendations made by the National Council on Radiation Protection and Measurements (NCRP). For states which have signed an agreement with the NRC, these regulations must be compatible with those regulations adopted by the Commission.

Question 3. How effectively are the regulations enforced?

Answer. The answer to this question is difficult, since to measure effectiveness demands a criteria or measuring stick as to what is effective and what is not effective. Many means could be used to measure effectiveness. In the case of a regulatory program, which enforces regulations, it appears that one of the better measuring sticks is the frequency of compliance and non-compliance by the radiation user. Therefore, using compliance as a way to measure effectiveness, most every state which responded, has indicated that there has been a substantial increase in the number of radiation users that are currently found in compliance compared with the percent of users that were found in compliance at the beginnings of their enforcement programs. As an example, one states experience showed that from the compliance records of 1965 through 1972, only 50 percent of dental facilities were in compliance with the adopted regulations. The record for 1977 indicates that 95 percent of dental facilities inspected were found in compliance with the regulations.

In the enforcement of the regulations, states have indicated various regulatory actions that are taken such as the suspension of licenses, the issuance of various orders and the actual closure of an x-ray department.

Question 4. Do the various states have adequate resources to assure reasonable compliance with these regulations?

Answer. The answer to this question depends upon the state being questioned. A few states feel that they have adequate resources to assure compliance with the regulations. However, a great majority of the state radiation control programs do not feel they have adequate resources to carry out all the things which they feel should be done. Specifically, it appears that where there are limited resources, the regulatory programs are concentrating their efforts in a very effective manner on prioritized items which have the greatest significance for unnecessary exposure to the population, but only limited attention is being paid to areas of low priority which, if resources were available, the entire spectrum of regulatory control could be implemented. For clarification, some of these areas of low priority are significant in the reduction of unnecessary exposure of our population.

Question 5. Please provide more detail on what form of control of non-ionizing sources exist at the state level.

Answer. Again, the type of control of non-ionizing sources depends on the state being considered. Although several states have enabling legislation allowing for the adoption of regulations in the non-ionizing area, only a few have actually adopted regulations under this legislative authority. This is a specific example in which states have considered the application of their resources to areas in which the exposure of the population is greater, specifically, ionizing radiation, in lieu of expenditures in the non-ionizing area. One state does require the registration of all laser sources and the reporting of any overexposures from lasers which might occur. Although most states do not have regulations in the non-ionizing area, most states conduct some type of inspectional program, primarily on a request basis, of non-ionizing sources, especially microwave cooking ovens. In addition, at least one state has conducted a rather extensive study of the potential exposure in teaching institutions from the use of laser systems. Following that intensive study, a concentrated educational program was used to advise the users in those institutions on the safe use of laser systems. It should be mentioned, that as it relates to protection of the worker, several states do have regulations protecting the worker from non-ionizing radiation which, in most cases, is within the State Department of Labor.

Question 6. Please elaborate on your recommendation for more research in the bio-effects of microwave and radar frequencies.

Answer. There is a need for the establishment of population exposure limits for both microwave and radar frequencies. Such limits exist in the ionizing area and certainly appear appropriate in the microwave and radar area, since these frequencies are in constant use throughout the United States.

Question 7. Do you believe that research on the bio-effects of non-ionizing radiation is being conducted by the various federal agencies in a responsible manner and with an adequate level of funding?

Answer. I do not believe that I have all the necessary information to make a judgement in this matter. Specifically, I am not aware of the dollars that are being spent at the federal level on the bio-effects of non-ionizing radiation. I am aware that several federal agencies have conducted, and are continuing to conduct studies on the bio-effects of non-ionizing radiation, and that such research has been coordinated by the Office of Telecommunications Policy. It is my understanding that considerable research has been done in this area, yet no public exposure standards have been developed. One state in response to my questionnaire, indicated that they had referred several cases of abdominal cancer of young men who had worked several years calibrating radar devices for military aircraft, to NIOSH for study.

Question 8. How could research of the bio-effects of non-ionizing radiation be improved?

Answer. I fully support the concept of one agency at the federal level coordinating the various studies that are being conducted in a given area. I believe that through a coordinated effort, the most efficient expenditure of funds will be obtained and a reduction in duplicative efforts will be achieved. Also, through some type of centralized coordination it would be assumed that findings in various investigative research could be tied together as to the overall impact of the total significance of exposure to non-ionizing radiation.

Question 9. Please amplify your comments indicating that medical and industrial users have complied with applicable standards.

Answer. As indicated in answer Number 2, the regulations enforced by the states are primarily based on the Suggested State Regulations and the recommendations of the National Council of Radiation Protection and Measurements. Although, most current state regulations are more stringent than those that existed in 1960, in general, current regulations basically cover the same areas today as were covered in 1960's. Therefore, based on these adopted regulations and the enforcement of these regulations, a majority of states have found that the compliance rate with these regulations is better today than were found when the programs were beginning in the 1960's. One particular area where significant improvement has been made is in the area of collimation. In the 1960's a large percent of x-ray facilities had inadequate collimation. Although today we are still finding facilities that do not meet the requirements of collimation, percentage wise, the amount that does not meet such a collimation standard is low relative to those that were found during the 1960's.

Question 10. Please document your statement about unnecessary radiation exposure emitted by color television.

Answer. In my testimony on this matter of radiation from color television, I was simply using that example as one in which the general population could be exposed to ionizing radiation. This fact was documented both by the Food and Drug Administration and by various states for color television receivers manufactured prior to the adoption of the performance standard by the FDA relating to the manufacturer of television receivers. Since the implementation of this performance standard, it appears that this source of ionizing radiation exposure to the general population has been significantly reduced, and no longer constitutes a public health concern. In 1973 and 1974 one state did an extensive survey of the exposure to the population from color and black and white television sets, and of the number of sets studies, only one percent indicated any radiation problems.

Question 11. Are T.V. sets currently being sold emitting x-radiation?

Answer. Many electronic devices during their operation will emit electromagnetic radiation. Therefore, it would not technically be correct to say that T.V. sets are not emitting x-radiation at all. The question is the level. Several states have performed some surveys on the emission of x-rays from color television sets since the implementation of the Federal Performance standard and their findings have indicated that most of the units are well within the limits. It is the opinion of most state radiation control programs that television sets which are manufactured under the Performance Standard no longer represent a public health problem as it relates to the emission of x-rays.

Question 12. How is the general public exposed to lasers?

Answer. Laser systems are finding many uses in the areas of construction, communications, and to a more limited use in the medical area. Most teaching institutions, both at the college and high school level use laser systems for various studies and demonstration purposes. Additionally, laser systems can be acquired by individuals for private ownership and use in their homes. However, it appears that the greatest potential for exposure of the general public to laser radiation is in the entertainment field, such as rock concerts, in which laser systems are used to project unusual color designs for visual effects.

Question 13. With respect to your discussion of jurisdictional overlap among Federal agencies, are jurisdictional lines really unclear or is this regulatory maze merely cumbersome?

Answer. It appears that the jurisdictional lines are *both* unclear, and cumbersome to get through. As indicated in my testimony as it relates to the setting of exposure guidelines for medical x-ray, there appears to be confusion as to the jurisdictional lines between the EPA and the FDA. As related to the cumbersomeness of getting through the regulatory maze at the federal level, the statement that was made by one state adequately describes the problem. The statement was, "It is difficult enough to remember all the names without trying to determine the purpose of input of each group involved in emergency planning." One of the problems which may be causing the cumbersomeness in emergency planning is that there is no clear statutory mandate as to which agency should "carry the ball." As an example, EPA has developed guidelines for taking protective actions, but these guides have not been published in the Federal Register. As a result, states are unsure that all federal agencies will support the use of these guidelines.

Additionally, as mentioned in my testimony, the states are concerned about the non-uniform regulation of naturally occurring and accelerator produced radioactive materials. Again, at the federal level, there appears to be at least three agencies involved (NRC, FDA and EPA), but still no regulatory control of this type material in a uniform manner as is now being done with by-product materials.

Question 14. Please provide your opinion of the adequacy of federal guidance on medical x-ray use and emergency radiation plans.

Answer. In general, most states feel that excellent guidance has been provided to the states in the medical x-ray use through the Bureau of Radiological Health of the FDA. In particular states found that federal guidance given through training programs to states has been invaluable. Unfortunately, the availability of these excellent medical x-ray courses presented by the Federal Government have been substantially reduced and most states have identified this void of training as a problem. The Bureau has just recently provided state radiation control programs with a new technique for obtaining training. Specifically, a video player and monitoring system. State radiation control programs applaud the Bureau for this effort as one mechanism that may fill the strongly needed training gap in the medical x-ray area.

As it relates to the emergency radiation plans, I believe that most states feel that the Federal Government is truly trying to provide guidance in this area, but the guidance which is being presented to the states seems somewhat confusing and cumbersome. It would appear that a more direct simple approach of guidance in the emergency planning area would be more effective in the development of state radiation emergency plans, than is now being provided at the federal level. Some efforts are being made to simplify the system, such as the reduction in the items of NRC concurrence for a state plan, but there is still much which could be done to make the process clear and simple.

Question 15. What is the current status of state emergency radiation plans?

Answer. Again, this question has to relate to the specific state under review. Most states have a radiation emergency plan but the status of that plan varies as to its comprehensiveness depending on many factors such as the existance of fixed nuclear facilities within that state, and the availability of resources for the preparation or amendment of such plans.

Question 16. Are the states capable of responding adequately to a major radiation release?

Answer. This is another question which can only be answered as it relates to the specific states under consideration. Specifically, while some states feel that their plans and resources for responding to a major release are adequate to protect the public health and safety, most states have indicated that should a major release occur in which there was wide spread contamination, some assistance would have to be obtained from the Federal Government. Again, this capability of response relates primarily to that of resources. Efforts are being made at the federal level to train state personnel for responding to radiation emergencies. Specifically, the NRC sponsored courses in this area are extremely valuable to the states, and we can only encourage more such courses.

Question 17. What state problems are likely to arise from the storage of high level radioactive waste?

Answer. The establishment of high level waste repositories may necessitate the additional burden on a state, both financially and in manpower, to monitor such facilities to assure the health and safety of its citizens. Specifically, it may be necessary for a state in which a repository is located to establish monitoring wells on the peripheral of such sites which would require routine sampling and analyses by state personnel. Another problem identified is that there may also be associated with a repository above ground solidification or calcination beds. Therefore, in addition to the repository, there may be above ground processes which represent a potential for contamination of the environment.

Question 18. To what extent are the states involved in discussions with the Federal Government on this issue?

Answer. With the recent workshops established by the Office of State Programs in the Nuclear Regulatory Commission, specifically designed to discuss high level waste repositories with state personnel, most state radiation control programs feel that adequate opportunities are being provided for discussions of the issue. However; when a specific state has been identified as a potential state for siting of such a repository much more direct communication between state agency and the Federal Government must occur, and it would appear that the Federal Government is making efforts for this close communication.

Question 19. What major problems do you foresee with respect to proposals requiring the licensing of radiologic technicians?

Answer. There is no conclusive data available to indicate that licensure will engender serious inflation of radiological cost nor deprivation of radiological health services through licensure of radiologic technologists. For example, in a 1976 report to the legislature, the state of California concluded that its licensure program had "been successful in protecting the health of the public by education and training of operators in techniques to reduce unnecessary ionizing radiation." That report further asserted that no manpower shortage resulted from the licensing efforts. Also, in 1976 the American College of Radiology and The American Society of Radiologic Technologists issued a jointly prepared study which found that "mandatory licensure laws created no significant effect upon technological manpower in terms of recruitment, availability, and compensation in three states," and there were "no significant changes in the availability of delivery of radiological services." If there is a major barrier in this area of licensure of radiologic technologists, it would appear that the barrier is that of the acceptability of the licensing of these paramedical individuals by the medical community. There appears to be somewhat of a disagreement in the medical community as to the need for this licensing effort. Some states have been reluctant to institute licensure programs because of confusion over what benefits licensing has produced in terms of actual patient exposure reduction, and over what are considered to be the key elements which should comprise an effective licensure program. Leadership at the federal level has been sorely lacking in this area. We do understand that the FDA, pursuant to the recommendations issued in a recently released HEW report on Health Manpower Credentialing, is planning to begin an effort to develop voluntary recommendations relating to the qualification and credentialing of medical radiation personnel. While we applaud this endeavor, we feel it falls short of the goal of assuring that every operator is adequately trained and proven competent because of its inability to insure adoption and compliance with the recommendations on a national basis.

In respect to the training of persons using medical x-ray, I would like to express another concern of the states which has also been expressed at the federal level. Specifically, as reported in the Bureau of Radiological Health staff report entitled "Diagnostic Medical X-Ray Technologists: The Issue of Qualifications," dated January 19, 1975, "With the exception of 13,000 radiologists, who are expert in the use of radiation for diagnostic and therapeutic purposes, physicians are generally not trained in the principals and practices of radiation protection, and what radiologic training the non-radiologists physician does receive, either in medical school courses or during the clerkship or internship periods, is almost entirely concerned with part of physicians is particularly significant in view of the fact that the performance of the examination is largely delegated by physicians to more than 100,000 x-ray machine operators, many of whom do not possess formal credentials certifying their competence. The situation in many instances, then, is that of a supervisor untrained in radiation protection directing an equally untrained employee."

Although not directly related to the question, I feel a comment must be made again relating to the nonefficacious use of x-ray sources. The states strongly urge that the medical community establish better guidance for "when x-rays are needed."

Question 20. What percentage of "old" x-ray equipment (manufactured or assembled prior to promulgation of the FDA standard) should be inspected each year to insure that both workers and patients are adequately protected?

Answer. The frequency of inspections of x-ray equipment, whether it be old or new equipment, varies from state to state. As an example, many states do not differentiate between the age of equipment in respect to the need for inspections. Rather than depend upon the age as a priority for inspection, many states have established a priority of inspection based on facilities with high work loads, which receive more frequent inspections. As it relates to protection of the patient, the category of hospitals ranks high in inspections, primarily because of the number of patients being exposed, and therefore, having a more significant impact on the total public health. On the other hand, other states have found that they are able to inspect all x-ray facilities on a three year cycle again, regardless of the age of the equipment. Several states now have a contact with the FDA for the inspection of new x-ray equipment manufacture under the FDA Federal Performance Standard. In most cases, this type of inspection is over and beyond their routine inspection of x-ray equipment not under the Federal Performance Standard. As a general statement, most states with an x-ray inspectional program, do not distinguish between the age of equipment in their priorities of inspection. Priorities are based more on the potential for exposure of a large population, and old equipment receives the same type inspection as new equipment. In your letter you mention that "at present industry sources are inspected only once every five or six years." This five or six year inspection frequency may be accurate for industrial x-ray sources with very low potential for exposure of the worker, such as gauges. However, for those industrial x-ray sources which do represent a higher potential of exposure of the worker, for example industrial radiography, these type industrial x-ray sources are inspected, on an average, more frequently than the five or six year average stated in your letter. Some states inspect these type sources annually.

Question 21. Do you believe that microwave cooking oven standards set by FDA are adequate to protect the public health?

Answer. With the present knowledge of the bio-effects of microwave radiation, it is the general consensus of the states which responded to my questionnaire that the FDA standard is adequate. When one considers the normal distance that a person stands when operating such an oven and the occupancy time around such an oven, emission level provided by the standard is adequate. The actual exposure would be quite low and consistent with the exposure level developed by the Russians.

Question 22. Have you noted any efforts on the parts of governmental entities or manufacturers to make sure that consumers understand the potential hazards of products using nonionizing radiation?

Answer. Though efforts have been made at the Federal, State and local levels to educate the consumer relative to the hazards of microwaves, there probably has not been enough effort to make the general consumer completely comfortable with a microwave oven. Examples of the efforts which have been made include several pamphlets on microwave oven safety developed both by the FDA and some states. Of state activity in educational efforts, I have enclosed a copy of a publication by the State of Illinois which has received very wide distribution, not only in the United States but worldwide.

We also understand that FDA's Bureau of Radiological Health has, and is continuing to expand its information efforts utilizing the agency's consumer affairs personnel which are strategically located throughout the U.S. to respond to consumer inquiries concerning microwave ovens.

Question 23. When will the Federal/State task forces issue their final reports?

Answer. While many of the issues identified for task force work within the Conference may require two or three years for final results, the majority of the charges given these task forces are completed within one year. At least a major portion of the charges are expected to be dealt with during the year in which the assignments are made, and a report of their progress is required at the annual meeting of the Conference.

I would like to indicate that many of the above questions were based on my survey of approximately 40 percent of the state radiation control programs which responded to my questionnaire.

Again, I would like to thank you for the opportunity to clarify some of the points made in my testimony, and hope that the above information will be helpful.

Yours very truly,

CHARLES M. HARDIN,
Member, Conference of Radiation Control Program Directors.

Senator STEVENSON. Our next witnesses are Dr. Richard Setlow and Dr. Alvin Lazen representing the National Academy of Sciences.

Thank you, gentlemen, for joining us. You are welcome to summarize your statement if you would like.

STATEMENT OF RICHARD SETLOW, SENIOR SCIENTIST, BROOKHAVEN NATIONAL LABORATORY, UPTON, N.Y.; ACCOMPANIED BY ALVIN G. LAZEN, ASSOCIATE EXECUTIVE DIRECTOR, ASSEMBLY OF LIFE SCIENCES, NATIONAL ACADEMY OF SCIENCES

Dr. SETLOW. I shall read the statement.

Mr. Chairman, Senator Schmitt, I am pleased to appear before your committee in response to your invitation to the National Academy of Sciences for views on a proposal to have the Academy conduct a comprehensive study of the current state of knowledge of the health effects of nonionizing radiation. Such a proposed study also would encompass the suitability of existing standards for this form of radiation, as well as the need to anticipate and prepare for protection against radiation emitted by emerging technologies.

For purposes of identification, I am Dr. Richard Setlow, a biophysicist at Brookhaven National Laboratory, and a member of the National Academy of Sciences. One of my research interests is the biological effects of nonionizing radiation. Accompanying me is Dr. Alvin G. Lazen, the associate executive director of the Assembly of Life Sciences within the National Academy of Sciences.

I believe it would be useful to begin with a background summary on the role of the National Research Council and the some 7,400 scientists, engineers, and other specialists who serve on its 940 committees and subcommittees, panels, boards, and other ad hoc groups.

The Academy's congressional charter, under which the NRC operates, directs the Academy to "investigate, examine, experiment, and report upon any subject of science or art" whenever called upon by any department of the Government. The Academy has been engaged in such studies on behalf of the Federal Government for over 100 years.

Our most recent endeavors include such wide-ranging subjects as the relationship of air quality and health, how can research increase food production, how accurate are our estimates of national and worldwide mineral reserves, in what manner shall we meet energy demands of future generations, what are the effects of halogenated hydrocarbons on the concentration of ozone in the stratosphere, et cetera.

I should add that a number of the more significant studies have been statutorily mandated by the Congress, while others are undertaken upon the initiative of the executive branch. Thus, as you will note, the pending proposal for a study by the NRC of nonionizing radiation is a well-established approach for providing information and recommendation to the Federal Government on program matter with a high technological content.

Next I should list for you the past studies that have been performed by the National Research Council that are related to the subject of your present inquiry.

Studies have been carried out on the effects of microwaves on samples of Korean war Navy veterans who were exposed to microwaves in the form of radar. Reports on these studies were published in 1963 and in 1977. We have also reviewed the U.S. Navy's research program in nonionizing radiation and issued a report which both evaluated the ongoing research and suggested new directions for research for the Navy to perform in the field of both extreme-low-frequency and microwave radiation. At the moment we are about to transmit to the Navy a committee report on the "Biologic Effects of Electric and Magnetic Fields Associated with Proposed Project Seafarer," the antenna system proposed by the Navy for installation in the upper Michigan peninsula.

Late last year the National Aeronautics and Space Administration asked the Academy to perform an assessment of a research plan to determine the biological and ecological effects of energy transmission by microwaves, the research plan to be developed by outside experts under NASA sponsorship. The NASA request was considered by the appropriate NRC bodies and it was decided that a survey of broader scope and an assessment culminating in recommendations for future research should be performed. The broadened proposal includes all aspects of the biological effects of nonionizing radiation, including the effects of microwaves, but excluding visible light and the infrared range.

Based on an approval and authorization by the governing board of the National Research Council, a draft contract proposal outlining such a broad study was prepared and has been discussed with a number of Federal agencies, including the Office of Telecommunications Policy, the Environmental Protection Agency, the Departments of the Army, Navy, and Air Force, the Occupational Safety and Health Administration, and the Bureau of Radiological Health of the Food and Drug Administration. Other Federal agencies with an interest in nonionizing radiation exposure will also be contacted.

Several months ago, we were made aware that the Senate Committee on Commerce, Science, and Transportation, in reviewing the Radiological Control for Safety and Health Act of 1968, was considering mandating a study by the Academy on the biological effects of nonionizing radiation. Let me here explain that the Academy takes no position on the question of whether Congress should or should not specify the National Academy of Sciences to perform scientific assessments; however, it is the usual practice of the Academy when so mandated to negotiate a mutually acceptable contract with the appropriate Federal agency to perform a study.

The Academy study as currently conceived consists of two parts focusing on the biological effects of nonionizing radiation. The first part is a committee study. The Academy performs its studies by inviting experts in the field to accept appointment to a committee which addresses each specific question. The Committee on Biosphere Effects of Nonionizing Radiation will consist of a steering committee representative of the disciplines required to perform an effective study. For instance, we expect to have biologists, psychologists, engineers, physicists, and other appropriate persons. A number of subcommittees will be appointed, each to address itself to a specific part of the question. For instance, we will have a committee on mutagenic and developmental effects of microwaves, one on the effects of microwaves on behavior, one on effects on brain function, et cetera.

In the course of the study, the committee will call consultants to provide it with additional information, and the committee may hold public meetings, workshops, or symposia aimed toward gathering information from the widest spectrum of the scientific and lay communities. At the completion of the committee's deliberations, a report will be prepared that will include three major sections. In the first, the committee will arrive at conclusions, insofar as the availability of data will permit, regarding the biological effects of microwaves and other nonionizing radiation. In the second section, it will make recommendations, insofar as possible, to serve as a basis for safety guidelines for human populations. In the third section, it will identify those areas in which critical scientific information is lacking and thereupon recommend a research program by which that information may be obtained.

The second part of the proposal provides for a continuation and intensification of the epidemiological study on 20,000 Navy veterans of the Korean war exposed to microwaves as compared to 20,000 Navy veterans not so exposed. The epidemiological work just completed has been a study of the causes of mortality of the Navy veterans so exposed. Because microwave effects may be transient in nature, it is essential that the life history of illness be traced from the time of exposure to the present for those veterans who survive. A study on such a large sample of persons has not as yet been performed, and the remarkable resources available to the Academy in its medical followup agency are the best available to perform this study.

In your letter inviting the Academy to express its views concerning a congressionally mandated study, you have also asked whether the Academy might examine emerging technologies which may utilize radiation and the need to anticipate and prepare for protection against radiation emitted by these new technologies. Our current draft proposal does not provide for such a study. However, the subject matter is amenable to examination and could be addressed by an Academy committee. I should mentioned that the Academy is also developing a proposal to study the impact on the over-the-air communications systems and on other microwave-utilizing systems that would result from taking regulatory action on nonionizing radiation. The study can be performed in an interactive manner with the biological effects study.

Mr. Chairman, you have also requested the National Academy view of the suitability of existing standards for nonionizing radiation. The Academy speaks via published reports emanating from its appointed committees. Since no committee has yet reported relative to the suitability of existing standards, there is not yet an Academy view. However, I will be happy to present my personal view of the existing standards, should you so request.

Dr. Lazen and I thank you for this opportunity to respond to your request to present the Academy's views.

Senator SCHMITT [presiding]. Thank you, Doctor. We appreciate your testimony very much.

I would request that you present your personal view.

Dr. SETLOW. My personal view is that we know comparatively little about the long-range effects of microwave radiation on people and that this is a very difficult subject, more difficult than the long-range effects of ionizing radiation on people.

Senator SCHMITT. Would you like to explain why you perceive that difference in difficulties?

Dr. SETLOW. One of the big difficulties is technical. In the ionizing radiation field we have dosimeters. It took many years to get such devices that you could put out in the air and measure the radiation dose someone was exposed to.

These are not conventionally available for microwaves. Certainly biologists do not have ready access to such instruments, nor do we have personal dosimeters. People that work in the field of ionizing radiation, for example, usually carry badges. There are no such things for microwaves.

Trying to assess the exposure of the population to microwaves is a very crude average. We don't know how various peoples vary from that average, even if we knew the average. That is one difficulty.

The second is the effects of nonionizing radiation are much smaller per unit of dose, whatever that is, than ionizing radiation. In particular, the effects on simple molecules and simple cells are much more difficult to perceive than from ionizing radiation.

Therefore, we don't have a background of basic biology, if I could call it that, which enables us to extrapolate theoretically to large-scale systems, so we are forced to rely on experiments on animals and to collect what epidemiological data we can on people. We can't do the experiments on people. Even if we could do such experiments, they would probably be very poor ones. We are a very varied group of individuals and we react in different ways. We have very little background information to permit extrapolations.

Yet there doesn't seem to be any tremendous hazard, as far as one could perceive, from short-term studies at the present time.

My personal view is sort of semiconservative. I would adopt for the time being the present standard for occupational hazard and lower, certainly, the standard for people in general. I would worry about devices that get into homes; how are they going to be observed? How are you going to find out whether such devices really stay as they were first manufactured and not produce more radiation?

This is a different field than ionizing radiation. We don't have individual X-ray machines in houses. We don't sell them normally to people and say this machine is OK; I will come back in 10 years and check it. We don't have that sort of thing. We do for microwaves and other kinds of radiation. That is why I think the standard for the population as a whole has to be lowered—because we have no way of checking up really on the population as a whole.

Senator SCHMITT. By a factor of 10, or 100?

Dr. SETLOW. I would lower it by a factor of 10, subject to the notion that when one accumulates as much data as one has, one might want to lower it by a factor of 10 or raise it a factor of 10, or leave it there.

What I am really saying is, the data are very poor. While there's no good evidence that there's a bad effect at the moment, I don't want to be put in the position of saying there never will be a bad effect.

Senator SCHMITT. Are you suggesting that the initial thrust of research should be in the development of a technology to do further research, or do they have to go hand in hand?

Dr. SETLOW. I think they have to go hand in hand. As I stated, we cannot do the experiments on people. We must extrapolate to people from animal studies, using what little epidemiological data there are, such as the veterans of the Korean war.

In making such an extrapolation, however, from mouse to man, you really have to have a theory to base that extrapolation on. The theory, unfortunately, does not exist at the moment. That's why we have to learn more about what happens in the interaction of such radiation with cells and animals, or really groups of cells, before we can make such an extrapolation.

It's no good, however, doing such experiments unless you can measure how much radiation things are exposed to. It's no good having a good biological experiment and a lousy physical experiment. They both have to go together. There has to be a good impedance match between the two. There's no sense being precise about the radiation dose if we are very imprecise about the biology, and vice versa.

Senator SCHMITT. Would you expect trace components and trace elements to have a larger effect in biological processes relative to the interaction of nonionizing radiation than they do relative to the interaction of ionizing radiation?

Dr. SETLOW. My intuition—that is all it is—would say trace elements would have a rather negligible role to play in the interaction of nonionizing radiation, microwave radiation. They might have a small but appreciable role for something such as ionizing radiation.

Senator SCHMITT. Mr. Chairman, do you have any questions?

Senator STEVENSON. I am sorry I had to step out.

Do you have concerns about microwave ovens? Quite a number—36,000—were recalled recently by one manufacturer.

Dr. SETLOW. I have no direct knowledge. I do have concerns. My concerns are in the form that there is no easy way of checking up on such ovens once they have been installed in the home and used for an appreciable period of time.

Senator STEVENSON. You said that. But why? Why wouldn't it be easy to check a thousand microwave ovens in use and compare that to a couple thousand color television sets? That could be done after a few years to give a good average picture.

Dr. SETLOW. I think there is a fundamental difference. I think we know a great deal about what happens to color television sets, and usually the radiation level doesn't go up in those after construction. If they deteriorate, maybe they just don't work.

If a microwave oven has a slight defective gasket or something of that sort, as a function of time, the amount of radiation coming out of the container could go up. No one has an easy instrument to make a quick survey of that oven in a particular home. That's my concern.

Senator STEVENSON. In a particular home. It wouldn't be too difficult to——

Dr. SETLOW. To make a sample? Not at all. Easy to make a sample.

Suppose 10 percent of the ovens——

Senator STEVENSON. Are leaking?

Dr. SETLOW [continuing]. Are leaking; what do you do? That's my concern.

Senator STEVENSON. I think it would tell you something about the 90 percent.

Dr. SETLOW. That's my concern. What do you do? What do you do with the information?

Senator STEVENSON. What should you be able to do?

Dr. SETLOW. As I say, that's only a concern. That's not an overriding concern.

I think we have really—you know, part of the concern really arises because we have no good notion as to precisely how dangerous such things are. If we are close to the threshold—if there is a threshold—then we would be concerned about leakage. If we are far from the threshold of damage, then we are not concerned.

That is why I think we really need information, quantitative information.

Senator STEVENSON. Aren't you telling the committee that the Academy is well on its way to conducting a comprehensive study of all the current knowledge with respect to the biological effects of nonionizing radiation? Are you saying that?

Dr. SETLOW. I don't think so.

Dr. LAZEN. No. We are planning such a study. We have not begun the study. We are currently taking a draft proposal to various Federal agencies to touch base with them and find out if they are interested in having the Academy perform such a study.

Senator STEVENSON. This study would be a study of all the studies?

Dr. LAZEN. It would review and evaluate all of the available data as a first step.

Senator STEVENSON. Toward?

Dr. LAZEN. Toward next determining what can be learned from that data to set a safety standard; to advise these Federal agencies about what a safe level might be; and, most important, to recommend what research is needed if not enough research has as yet been performed.

Senator STEVENSON. I don't mean to be facetious, but how long would it take to conduct that study of all the studies to determine what studies are needed.

Dr. LAZEN. It's often been said the Academy keeps time by the calendar, rather than by the watch.

Academy studies do take some time. We predict this one would take 2 years to perform.

Senator STEVENSON. How much would it cost?

Dr. LAZEN. There are two parts to the study. One part is a committee study, which would give you the answers that you have just spoken about. It would be a $400,000 study over 2 years.

Another part to the study would make use of a unique Academy resource: The availability of the medical data of the Department of

Defense and the Veterans' Administration. Those data can be used to perform an epidemiological study of Korean war veterans exposed to radar. The purpose would be to try to determine whether their exposure to microwaves has had some health impact.

That part of the study would cost approximately $500,000.

Senator STEVENSON. How could we in the Congress move this process along? Is additional funding necessary? Is a congressional mandate necessary?

Dr. LAZEN. We would hope that our process of touching bases with the various Federal agencies would elicit enough interest from them that they would be willing to support such a study.

If, however, Congress mandates a study, it certainly facilitates matters.

Senator STEVENSON. Should that mandate include additional funding or do you think the funds are already available?

Dr. LAZEN. There are several new topics that have been introduced in the course of discussion.

The letter from Senator Magnuson requesting views from the Academy mentions a study of emerging technologies and the potential health effects of these emerging technologies.

That part is not included in our draft proposal.

It would require additional sums of money if that were also to be studied.

Senator STEVENSON. Don't you think that is important? By the time the study of studies is produced, the additional studies could be irrelevant, if it is not aimed at the circumstances at some time in the future.

You are not disagreeing with that?

Dr. SETLOW. I agree with that absolutely.

Senator STEVENSON. So that part of it at least might require funds in addition to those which might otherwise be available?

Dr. LAZEN. That is correct. The study of emerging technologies would be a difficult one. It involves looking into a crystal ball within a crystal ball—looking at emerging technologies and then trying to predict what health effects might result from those.

Senator STEVENSON. Has the Academy made recommendations to the Navy with respect to Project Seafarer?

Dr. LAZEN. Yes. The final report should be available within 1 month. A preliminary report was transmitted to the Navy in November 1976.

Senator STEVENSON. What did the preliminary report say?

Dr. LAZEN. The preliminary report said that along the antenna the effects of the electric fields and the magnetic fields are so small that they probably present no hazard to health. At the ground terminal of that antenna system, there is a higher electric field, and some potential hazard exists.

Senator STEVENSON. At which end?

Dr. LAZEN. At the ground terminal, at the end where the antenna goes deep into the ground.

Dr. SETLOW. And is connected to the Earth.

Senator STEVENSON. The final report will say the same thing?

Dr. LAZEN. The final report will be in line with that. We will know exactly what it will say in a month.

Senator STEVENSON. Have you considered the biological effects on people in the vicinity of the transmitters which transmit the signals to satellites for communications purposes? The receivers would receive a very weak signal, but the transmitters send out a pretty strong signal. Has anybody looked at what those do to people in their vicinity?

Dr. LAZEN. The committee looked at the entire Seafarer system.

Senator STEVENSON. Does that describe the Seafarer system?

Dr. SETLOW. The two systems, Seafarer, and the microwaves we were speaking about, are completely different. The microwaves are very high frequency radiation that is beamed to the satellites, usually via relatively small antennas.

Senator STEVENSON. Excuse me. If I may interrupt on that point. These antennas, transmitters, whatever they are, are not all small. The ones I see are certainly larger——

Dr. SETLOW. I call that small.

Senator SCHMITT. Compared to Seafarer?

Dr. SETLOW. Compared to Seafarer. They are relatively small, the size of this room. That is still relatively small by such constructions.

Seafarer, on the other hand, is low frequency radiation. The frequencies are very close to those used in our powerlines every day, 60 hertz.

In order to radiate such energy, it requires a tremendous antenna or grid of wires. It cannot be focused. You can't build an antenna large enough to focus it. One of the proposed projects encompasses a good portion of the Upper Peninsula of Michigan, for example. That I call large.

The problems of Seafarer and microwaves are completely different electrically and biologically.

The Project Seafarer that has been alluded to is the long wavelength one. Our report on that will be out shortly.

It is difficult to see where one would collect good epidemiological data for this kind of radiation, unless such a project were begun.

That is no reason, of course, to begin it, whereas there are epidemiological data from microwaves, poor as they might be.

The analysis is completely different in these two cases.

They both come under the heading of electromagnetic radiation, but they really are almost as completely different as X-rays and ultraviolet.

Senator STEVENSON. Let's get back to my question. What about the high frequency microwave transmitter for satellite communications? Does that pose a danger to people in its immediate vicinity?

Dr. SETLOW. I don't know, personally.

Senator STEVENSON. Does anybody know?

Dr. LAZEN. We just do not have information on that.

Senator STEVENSON. Nobody does.

Dr. SETLOW. If there were big effects, they would have been observed. The problem in all this work is what about small effects? All one can say is no large effect.

Senator STEVENSON. Are the effects of nonionizing radiation cumulative?

Dr. SETLOW. No good data. If I can interject, that really depends on the mechanism of what the effects are, whether one can make such an extrapolation. Unless we know that, we can't really make that extrapolation.

Senator STEVENSON. We have a rollcall now.

Senator Schmitt, any questions?

Senator SCHMITT. Very quickly, in the National Academy's defense, I think it would be useful if you would explain in a minute or two how you put together your study teams. I think it is important to realize that you are drawing people from the scientific community who are being paid to do a lot of other jobs besides donating some of their time to the National Academy. A 2-year period for a study is a reasonable length of time in that environment.

As a matter of fact, as I understand it, it is extremely difficult to do a short, quality study utilizing the Academy's resources.

Dr. LAZEN. The committee can be put together in various ways. Let's talk first about the nature of the committee.

In an area where a topic is not very sensitive, where a scientific judgment based on fairly hard data is the topic, one can call upon the recognized experts in that field and ask them to deliberate the question and come up with their best scientific judgment. When study of the subject area involves asking for an evaluation based on a small amount of data and especially if the area is extremely controversial, with the experts at different poles, we sometimes have to form a committee of scientists who are somewhat at a distance from the field itself.

These are statesmen of science, people who can understand the science quite well, but who have not been labeled on one side or the other of the controversy.

Then these people will call in the experts or consultants who will present the information before them.

The statesmen of science then have the opportunity to assess and evaluate what they are hearing and determine what they think is good admissable evidence and what is not.

It is a court of science to some degree. It is not an adversary proceeding, however. It is a scientific investigation.

I would think for the microwave study we might want to use this approach, though it isn't by any means certain. We would want to get statesmen of science on the steering committee at least and have them hear testimony from the experts, those who have performed the actual work.

Now, the method of forming a committee, that is for determining the names of the committee members, we rely first on our Academy members. There are 1,100 members of the National Academy. We ask those persons knowledgeable in the field to recommend to us others who are expert in the field or who might be appropriate for the committee. A list of potential nominees is then gathered, and there are several review steps.

We will be looking for a balanced committee. Therefore, we will go through two or three levels of screening, evaluating the nominees and finally determining in our opinion the best composed committee to address the topic.

Senator SCHMITT. Thank you. I think that clarifies that.

Finally, and even more quickly, do you think there is any danger that, in studying and evaluating the emerging technologies, you will create an environment in which certain emerging technologies may not be pursued? Will you be prematurely discouraging research in the emerging technology?

Dr. SETLOW. No. Not at all. I think one of the goals we would like to achieve is to make long-range predictions of environmental hazards, before it is too late. I think the best example we have had recently is the long-range predictions of depletion in ozone in various technologies. That is really a long-range prediction. It gives us plenty of time to adapt—even though it may seem a little painful at the moment—to adapt to such predictions, so the environment will not be altered drastically. I think that is the goal of these predictions.

Thank you, Mr. Chairman.

Senator STEVENSON. Thank you, Dr. Setlow. The committee will now recess for as long as it takes us to vote.

[The following information was subsequently received for the record:]

QUESTIONS OF THE COMMITTEE AND ANSWERS THERETO

Question 1. The NAS proposed study on the biological effects of non-ionizing radiation was initially stimulated by a NASA request for the Academy to review a research plan "to determine the biological and ecological effects of energy transmission by microwaves . . ." Does the current proposal by the National Academy of Science for a broader study include an examination of the biological and ecological questions that may be raised by a satellite solar power system beaming energy via microwaves? If not, would you consider it feasible to examine these questions in the context of the currently proposed study?

Answer. In the Academy's proposed study, all available data concerning biosphere effects of microwaves will be collected and evaluated. Where necessary information is not available due to a lack of research data, the Committee will recommend research needed to provide the information.

Thus NASA (and other agencies) will be provided with (1) an evaluation of the biological and ecological effects of microwaves whether they originate from the solar satellite or other source and (2) a research plan for filling gaps in the information independently recommended by the Academy Committee, with which the agency may compare its own research plan. We suggest then that NASA's requirement will be met for an examination of the biological and ecological effects attendant upon a satellite solar power system beaming energy to earth via microwaves.

Question 2. Please provide the Committee a copy of the draft contract proposal on the biological effects of non-ionizing radiation currently being circulated among the agencies.

Answer. I have enclosed a copy of the draft contract proposal used as a starting point for discussions with representatives of EPA, FDA, OTP, OSHA, and DOD. The proposal is now undergoing extensive revision. The epidemiological study will be described in far greater detail in our final proposal. We plan to extend the scope of the proposal to include (1) the question of emerging microwave-employing technologies and their possible biosphere effects and (2) the "impact" study as described under item 3. In so expanding the study, the Assembly of Life Sciences and the Assembly of Engineering will assume joint responsibility for performance of the study in a closely coordinated fashion.

Question 3. In your prepared comments, you state "the academy is also developing a proposal to study the impact on the over the air communications systems and on other microwave utilizing systems that would result in taking regulatory action on non-ionizing radiation." Please provide more detail on this proposed study. What is the current status of this proposal?

Answer. The Assembly of Engineering is planning a two-year study of the impact on existing and future over-the-air telecommunications systems that would result from significant changes in radiation level standards. The scope of the study would include a review of the results of ongoing monitoring efforts; a survey of steps taken by telecommunications system operators and telecommunications equipment manufacturers to comply with existing standards; the identification of those portions of existing telecommunications systems that cannot comply with current standards or would fail to comply if the existing standard were made more stringent; a review of telecommunications technology that could alleviate the radiation problem; the prediction of the steps that would need to be taken so that telecommunications systems portions identified could comply, and an estimation of their cost; and recommendations on federal policies or legislation that may be required. A multidisciplinary panel is envisioned consisting of experts in electrical and electronics engineering, radio and wired telecommunications technology, space communications, military communications, telephone networks, radio broadcasting, television broadcasting, medicine, psychology, and public affairs. A detailed proposal is now being developed by a unit of the Assembly of Engineering.

Question. 4. Epidemiological studies on the Korean War veterans exposed to microwave have been criticized in some quarters as being basically inconclusive because of the lack of sophisticated instrumentation capable of recording the dosages received by the men or the power density of levels to which they were exposed at the time of exposure. Please comment.

Answer. In response to your question concerning criticism of the epidemiological study, it is, of course, true that the dosages received by Korean War Navy veterans are not known. They were not measured at the time, nor would it have been practical to do so. For lack of information on doses, resort has been had to a "Hazard Index" instead. The Hazard Index is constructed for a man by considering when and how long he served on each ship, while each ship, in turn, has been classified according to the power of the radio equipment aboard at different times. The Hazard Index thus measures, not what a man received by way of microwave radiation, but what he might, potentially, have received.

Men whose Hazard Indexes are small almost surely had small doses. On the average, men whose Hazard Indexes are very large can be assumed to have received larger doses than men with small Indexes, even if we cannot specify exactly what the doses were.

Viewing the problem more broadly, it is fair to say that, for much human risk assessment, measures of "dose" will be sadly inadequate when assessed by the standard of an investigator in the laboratory who is able to expose animals to measured doses. This lack of precision is equally true of studies of the effects of diagnostic X-ray and of exposures to noxious chemicals. When health effects are small and difficult to measure, or dramatic but infrequent (as in the induction of leukemia by X-rays), to decide whether there *are* effects on humans requires the study of very large numbers—thousands—of persons over very long periods of time. The only feasible and economic way of conducting such epidemiologic studies is to take advantage of experience which has already occurred.

Under these circumstances, the observer is in no position to control the circumstances of exposure, nor to guarantee a recording of its intensity.

For example, neither Stewart nor MacMahon in examining the relationship between X-rays and leukemia could tell, from records, what dose was received per X-ray in their studies of the effects of radiation on the fetus. Often, they could not tell even how many X-rays had been made. Nevertheless, they obtained clear-cut differences in subsequent childhood cancer rates between the exposed children and those not exposed.

Although it would not be difficult to design a good study of the effects on man of long-term exposure to moderate levels of microwaves, the exercise is impractical because of the expense of performing such a study and the ethical issues involved in experimenting upon humans. Even if carefully measured and documented exposures could be made, one would have to wait several years to ascertain the outcomes, assuming one could succeed in keeping the study subjects under observation.

In brief, the justification for the Korean veteran study is not that it is ideal, but that, at the present time it represents the best that can be done as a practical matter. The choice is, given the imperfections, shall we learn what we can—or shall we simply ignore the problem.

Question 5. Approximately how much additional funding would a study of the emerging technologies and the potential health effects of these emerging technologies require?

Answer. The contract proposal already circulated among several agencies called for a committee study of two years duration of the biological effects of nonionizing radiation at an estimated cost of $400,000 and an epidemiological study, three years and $500,000. The revised and expanded proposal will include the "impact" study, two years and $320,000, and the "emerging technology" study, two years and $250,000.

PROPOSAL FOR REVIEW OF THE BIOLOGICAL EFFECTS OF MICROWAVE AND OTHER NONIONIZING RADIATION

SUMMARY

Devices emitting nonionizing electromagnetic radiation are widely used in public and military applications, such as telecommunications, radar, microwave ovens, diathermy treatment, and electric power transmission. Future use of microwaves is expected to increase dramatically. Yet data concerning the biological effects of microwave and other nonionizing radiation—including radiations, radio telephone systems, CB radios, radar devices and systems, satellite inadequate for the purpose of establishing protection guidelines for populations exposed, and to sources of microwave and other nonionizing radiation, for estimating potential risks to those populations. This project will entail a critical review and evaluation of the existing scientific knowledge on human and laboratory animal exposure to microwave and other nonionizing radiations. The purposes of the project will be to:

Arrive at conclusions regarding the biological effects of microwave and other nonionizing radiation,

Make recommendations insofar as possible to serve as a basis for safety guidelines for human populations, and

Identify those areas in which critical scientific information is lacking and recommend a research program by which that information may be obtained.

ORIGIN

Renewed interest and some concern have emerged regarding the health effects and safety of microwave ovens, extra low-frequency radiation, and nonionizing radiation from power transmissions:

News reports concerning the beaming of microwaves into the American Embassy in the Soviet Union began a series of speculations about potential health hazards to personnel involved. The Department of State has contracted for an epidemiological study to investigate this specific allegation.

A two-part article by Paul Brodeur in The New Yorker, December 1976, has heightened public consciousness of the lack of information and possible hazards associated with exposure to microwave radiation.

Considerable interest and controversy have arisen concerning plans to construct an extremely low-frequency signal transmission system to be used by the U.S. Navy (Project Seafarer). The ALS has studied this issue exhaustively.

The numbers and kinds of sources emitting microwave and other nonionizing radiation are rapidly increasing in this country and elsewhere. Television stations, radio telephone systems, CB radios, radar devices and systems, satellite communications systems, microwave ovens, industrial applications, and power transmission lines are among the sources of nonionizing radiation in wide use. Diathermy and some cauter-and-incision devices make use of the thermal properties of microwave radiation for their medically useful effects. 1970 NIEHS report titled Man's Health and the Environment . . . Some Research Needs states that . . . the widespread use of microwave generators . . . has reached such an extent that one might conservatively estimate that nearly one-half of our population lives in a measurable microwave environment. Increased urbanization will move greater numbers into an energy field which did not exist one hundred years ago (p. 106).

The proliferation of existing as well as future systems that will utilize or produce nonionizing radiation calls for an intensive evaluation of potential hazards to exposed human populations and other biological systems.

The U.S.S.R. and other eastern European countries have reported extensively on non-thermal, low-level effects of microwave radiation. The accepted safety standard in Russia for exposure to microwaves ranges from 100 to 1,000 times less than the standards set in the U.S.

Previous committees of the National Research Council have been involved in this area. In 1963 and 1977, the Medical Follow-Up Agency/ALS reported on the effects on Navy Veterans exposed to radar emissions during the Korean War. This study is the most comprehensive epidemiological work performed on humans exposed to microwave radiation. The study group included about 20,000 Navy veterans exposed to radar who were compared to about 20,000 closely matched Navy veteran controls. An Ad Hoc Committee on the Navy Nonionizing Radiation Research Program/ALS released its report in 1974. The Committee on the Biosphere Effects of Extremely Low-Frequency (ELF) Radiation/ALS is scheduled to release its report to the Navy in mid-1977. Information gathered in this intensive study of the effects of ELF on humans and the ecosystems will be current and useful in fulfilling the task outlined in this proposal. The Assembly of Behavioral and Social Sciences and the Assembly of Engineering have studied or are currently studying ocular effects of microwave radiation and microwaves generated in telecommunications.

In September 1976, the National Aeronautics and Space Administration (NASA) requested the ALS to review the research priorities set by NASA for studying biological effects of microwave radiation as they relate to the solar energy satellite program.

Public Law 90–602, "Radiation Control for Health and Safety Act of 1968," is scheduled for Congressional review and possible change. Staff of the Senate Commerce Committee and an analyst in biological sciences for the Congressional Research Service, Library of Congress met with ALS staff members in February 1977 to discuss the possibility that in amending PL 90–602, the Congress may request the National Research Council to conduct a thorough review of the existing knowledge of the health effects of microwaves and other nonionizing radiation.

PROPOSED PLAN OF ACTION

The proposal is envisioned as involving two independent but interrelated parts.

Part 1: A committee will be established that will have the following charge:

Review and assess the existing data on the biological effects of microwave and other nonionizing radiation. The biological effects studied will include evaluation of the somatic, behavioral, and genetic effects determined from observation of humans and predictable from animal models. Evaluation will also be made of the effects on other biological systems such as microbes, plants, and animals. The impact of microwave and other nonionizing radiation on the entire ecosystem also will be assessed.

Determine the research priorities for each of the issues above.

Where information is adequate, provide estimates which may be useful for establishing guides for protection, if necessary.

The Committee membership will include biologists, ecologists, engineers, physicists, medical specialists, geneticists, psychologists, and other scientific disciplines as required.

Panels and subcommittees, each chaired by a member of the Committee and consisting of "outside" consultants and experts, will be formed to address specific issues.

In addition to the regular committee meetings, public meeting(s), symposiums and conferences may be conducted to meet the goals of this project.

Part 2: The epidemiologist study of Navy veterans will be extended and refined.

Evaluation of the effects of environmental insults on human health is notoriously difficult. Despite decades of experience with X-rays, there is still no consensus among informed scientists concerning the risks associated with small doses of X-rays delivered at a slow rate. Experiments with laboratory animals have elicited a variety of biological effects that X-rays can produce, but the characteristic effects vary from species to species, and even from strain to strain among mice and rats: the very shapes of the dose-responsive curves are different between Sprague-Dawley and other kinds of rats.

The problems that are merely difficult with respect to X-rays become nearly impossible when extended to microwaves. Cancer induction, our chief concern in regard to X-rays, is objectively verifiable; cancers are as easily diagnosed in a mouse as in a man. The Russian literature, at least, on microwave effects, speaks of subtle neurological effects much more difficult to assess than cancer induction and the task of risk evaluation becomes, correspondingly, more complex.

For two reasons, then, assessment of risks to humans depends upon the study of humans: We cannot with confidence extrapolate from mouse to man; and man can tell us things about his mood and his performance, whereas animals cannot.

An epidemiological study of morbidity will be performed comparing the exposed group of Navy veterans to the controlled group of Navy veterans.

ANTICIPATED RESULTS

A final report will be prepared in which conclusions are drawn regarding the known and/or potential biological effects of microwave and other nonionizing radiation, focusing on the biological risks to exposed human populations. It is expected that such conclusions will serve as a reliable base upon which reasonable protection guidelines may be established if deemed necessary, including the length and levels of exposure of various populations of chronically and acutely exposed individuals, and performance standards for various electronic products that emit microwaves or other nonionizing radiation. The final report will identify those areas where critical information is lacking and recommend research priorities.

It is anticipated that symposium proceedings resulting from the review will be published as part of this project.

ESTIMATED COST

Part 1 can be accomplished in 24 months at an estimated cost of $400,000. It is estimated that Part 2 of this proposal can be accomplished in 36 months at an estimated cost of $500,000.

The following table shows the proposed schedule of performance and an estimate of costs.

	1st yr	2d yr	3d yr
Pt. 1	$200,000	$200,000	
Pt. 2	120,000	190,000	$190,000
Total yearly cost	320,000	390,000	190,000
Total estimated cost		900,000	

[Recess.]

Senator Stevenson. The committee will come to order. The next witness is Mr. Richard Bauer, president of the American Society of Radiologic Technologists.

Once again if you would prefer to summarize, we would be happy to enter your statement into the record.

STATEMENT OF RICHARD BAUER, R.T., PRESIDENT OF AMERICAN SOCIETY OF RADIOLOGIC TECHNOLOGISTS

Mr. Bauer. I have a brief report, Mr. Chairman. I think I will read it, the entire report.

Senator Stevenson. Very well.

Mr. Bauer. Mr. Chairman, members of the committee, my name is Richard Bauer. I am president of the American Society of Radiologic Technologists. We welcome the opportunity to appear before you today during these oversight hearings on radiation health and safety, and we commend the committee for its attention to this very timely subject.

For years the American Society of Radiologic Technologists has expressed its concern regarding unnecessary medical radiation to the patient-consumers of this country. In May of 1968 during consideration of H.R. 10790 (Public Law 90-602) we testified before this committee and stated:

> We can understand the justification for regulation and improved standards if public health is to be adequately protected. . . . The American Society of Radiologic Technologists wishes to make a matter of record the firm conviction of all its members that patient exposure should be reduced to the absolute minimum necessary to provide appropriate diagnostic information.

Enactment of the Radiation Health and Safety Act of 1968 has given impetus to the reduction of unnecessary medical radiation by the establishment of performance standards for radiologic equipment, but no equipment can be any better than its operator. Any and all radiation emitted by properly calibrated equipment is produced solely at the will of the operator. Radiation is not detected by the senses of sight, hearing, touch, smell or taste. Without sufficient knowledge of its use, the operator has the potential to damage not only the patient's health but his own as well.

Moreover, the patient-consumer is rarely in a position to judge either the qualifications of the operator or the quality of the examination. The use and abuse of radiation is deserving of due consideration. Again, we are encouraged to have this committee share our concern.

Since the enactment of Public Law 90–602, the American Society has gone on record in each succeeding Congress in support of the enactment of Federal minimum standards of education for radiologic technologists. There are currently an estimated 130,000 to 150,000 operators of radiologic equipment in this country. Approximately half of these individuals have voluntarily submitted to examination and have met the educational standards prescribed by the profession. The remaining 50 percent have no officially recognized qualifications.

At the request of the Department of Health, Education, and Welfare, there was a moratorium on the licensing of additional allied health personnel from 1971 to 1975. During these 4 years the subject of credentializing health manpower was studied. In June 1976, a preliminary report was prepared by the Subcommittee on Health Manpower Credentialing of the Public Health Service Manpower Coordinating Committee entitled "A Proposal Credentialing Health Manpower." At that time the Department invited the official reaction of the States and appropriate professional organizations to the recommendations contained in that preliminary report.

Although we understand that the final report on credentialing health manpower may soon become available, its preparation has required an extended period of time. There has been no discernible progress in this important area since the moratorium was first imposed in 1971.

Further, we are satisfied that the implementation of any recommendations with reference to credentialing health manpower will be a very lengthy, time-consuming process. Until this report is released, it is not possible to comment further.

Although there has been no definitive development that we are aware of, it is our understanding that the Environmental Protection Agency is in the process of developing Federal radiation guidelines for diagnostic X-rays to reduce unnecessary radiation exposure of patients, including that caused by inadequate operator preformance. These guidelines, which will apply to Federal agencies when approved, were developed under the authority of the former Federal Radiation Council, the functions of which were transferred to EPA in 1970. These guidelines, which were prepared by an interagency working group of senior medical officials from the military and the Veterans' Administration, were published in the Federal Register of January 26, 1977, page 4884, and are indeed a step in the right direction. We have been told that these guidelines are still in the process of being finalized.

We commend the Federal Government for asserting this much needed leadership, and we are indeed hopeful that these guidelines, several of which relate directly to the qualifications of operators of X-ray equipment, will receive the President's consideration and approval at an early date.

However, as I pointed out, these guidelines, when approved, will be mandated only for Federal facilities using diagnostic X-rays.

In the absence of conclusive action by a Federal agency, the American Society of Radiologic Technologists continues to believe the Federal legislation is the best approach to insure operator competence in the use of X-ray equipment. At present legislation is pending in both the Senate and the House to provide for the protection of the public from unnecessary medical exposure from ionizing radiation.

Mr. Chairman, your committee will be interested to learn that the American Society of Radiologic Technologists at its annual meeting here in Washington last week, which was attended by more than 2,000 members, unanimously adopted resolutions in support of the enactment of S. 1695, the Radiation Health and Safety Act of 1977, introduced in the Senate by Senator Jennings Randolph and, its companion bill in the House, H.R. 4573, introduced by Congressman Edward I. Koch. I would like to request that these resolutions be made a part of the record.

Senator STEVENSON. The resolutions will be entered in the record.

Mr. BAUER. On behalf of the American Society of Radiologic Technologists, I appreciate the interest of the committee in reviewing this important aspect of health care, and will be pleased to respond to any questions the committee may have.

Senator STEVENSON. Thank you, Mr. Bauer.

You say about half of the 130,000 to 150,000 operators of radiologic equipment in the country have met the educational standards prescribed by the profession. I gather from that estimate you don't have a very precise idea of how many operators there are in the country?

Mr. BAUER. No, we do not have a precise estimate.

Senator STEVENSON. The other 50 percent have no officially recognized qualifications. What does that mean? They could be operating this equipment with no appropriate training?

Mr. BAUER. That's right.

I would like to back up just a minute, Mr. Stevenson.

As far as the qualified operators, we have records from the American Registry of Radiologic Technologists. I don't have the figures with me, but there are approximately 60,000 to 65,000 certified by the American Registry of Radiologic Technologists and currently operating in the field. The exact percentage is the thing that I am in question about because we don't know the total number operating in the country.

Senator STEVENSON. What are the bases for your certification?

Mr. BAUER. A minimum of 2 years' education in a program approved by the American Medical Association; and followed by examination by the American Registry of Radiologic Technologists.

Senator STEVENSON. What does the AMA require in the way of education?

Mr. BAUER. Our programs are approved by the AMA. The details within the program?

Senator STEVENSON. What kind of curriculum?

Mr. BAUER. Anatomy, physiology, radiation safety, radiation biology, radiographic positioning, medical ethics, and other appropriate subjects.

Senator STEVENSON. You get that kind of training at medical schools?

Mr. BAUER. These are programs specifically designed for X-ray technologists.

Senator STEVENSON. At accredited medical schools?

Mr. BAUER. The majority of the programs are operated in hospitals approved for that purpose by the AMA. There are some college-based programs in area hospitals.

Senator STEVENSON. Are those who are certified required thereafter to periodically upgrade their training, keep abreast of newly developed equipment and techniques? Are there any postcertification programs?

Mr. BAUER. At the present time, there is no requirement for continuing education; but the American Society has instituted a voluntary program of continuing education for those who wish to document their evidence in continuing education.

Senator STEVENSON. The other 50 percent, there aren't any qualifications at all established?

Mr. BAUER. No qualifications at all, sir.

Senator STEVENSON. Don't one or two States have——

Mr. BAUER. There are, I believe, 12 States that now have licensing laws enacted. Not all of them have been fully implemented so far.

Senator STEVENSON. When those laws were or are implemented, there will be a licensure or certification procedure for all technicians?

Mr. BAUER. Generally speaking, licensed practitioners are exempt from this type of legislation; but anyone who is not a licensed practitioner will be required to have a license in order to expose another human being to ionizing radiation.

Senator STEVENSON. In those States?

Mr. BAUER. In those States.

Senator STEVENSON. How adequate are those testing or licensure procedures in the few States that have them, in your opinion?

Mr. BAUER. There is wide variation in the present licensing laws.

One of the things the American Society is going to take a look at this year is a comparison between these existing licensing laws. We want to draw comparisons, educational requirements, the makeup of the board of examiners, fee structures, continuing education requirements, this sort of thing.

The entire formula has not been developed yet. This is one of the things we will be looking at during the coming year.

Senator STEVENSON. Do you have any more observations to make about the equipment? Is the old X-ray equipment being upgraded, modernized rapidly? What should be done to make sure that it is, if anything, and that it is maintained properly?

Mr. BAUER. Well, I don't think our society is in a position to evaluate that sort of thing.

Senator STEVENSON. It is too technical?

Mr. BAUER. It is a different area. It would be more related to the program directors, the gentlemen who spoke a few moments ago. It would be in their area, rather than within our society.

We discussed back and forth among each other what new equipment is going into this particular hospital. We don't have any scientific data on that.

Senator STEVENSON. Aren't radiologic technologists exposed to radiation depending in part on the quality of the equipment? Wouldn't that be a basis for some concern?

Mr. BAUER. We are concerned about it, but we also are very careful about it. It is an important part of our own education. I am sure every technologist in the country is aware of it, cautious about it; but as I say, I don't know just how this is being done on a national level. It could be an individual effort by the various hospitals, each individual technologist.

Senator STEVENSON. Are technologists monitored periodically? Is there any program to do that, to determine what the cumulative effects of their exposure is?

Mr. BAUER. Yes. As far as I know, every technologist in the country wears a film badge or a detection device of some kind to determine accumulated radiation.

Senator STEVENSON. That is voluntary?

Mr. BAUER. I believe it is mandatory.

Senator STEVENSON. Who would mandate it if it were mandatory?

Mr. BAUER. It may be mandated by the various State boards of health, that's a possibility.

Senator STEVENSON. Thank you, Mr. Bauer. That is very helpful.

If any of the other members have any additional questions, we will take the liberty of asking them of you in writing.

Mr. BAUER. Please do that.

[The documents referred to follow:]

RESOLUTION IN SUPPORT OF SENATE BILL 1695

(Radiation Health & Safety Act of 1977)

Whereas, The American Society of Radiologic Technologists is a national professional organization of radiologic technologists certified by The American Registry of Radiologic Technologists; and

Whereas, the Society perceives the problems inherent in the equitable distribution of health care to persons at all socioeconomic levels in all geographic locations; and

Whereas, the Society appreciates the dangers implicit in exposure of the public from sources of radiation; and

Whereas, since 1968, the Society has supported federal minimum standards of not less than two years of education for operators of medical equipment emitting radiation; and

Whereas, the Society is convened in Washington, D.C., June 17–23 1977, and believes it appropriate to express concern about unnecessary radition exposure of patients caused by operators of equipment who have less than the established standards: therefore,

Be it resolved: That The American Society of Radiologic Technologists continues its pursuit for the enactment of federal minimum standards of education for radiologic technologists; and

Be it further resolved: That the members of this Society go on record in support of S. 1695, as introduced in the ninety-fifth Congress, by the Honorable Jennings Randolph (W. Va.).

RESOLUTION IN SUPPORT OF HOUSE BILL 4573

(Radiation Health & Safety Act of 1977)

Whereas, The American Society of Radiologic Technologists is a national professional organization of radiologic technologists certified by The American Registry of Radiologic Technologists; and

Whereas, the Society perceives the problems inherent in the equitable distribution of health care to persons at all socioeconomic levels in all geographic locations; and

Whereas, the Society appreciates the dangers implicit in exposure of the public from sources of radiation; and

Whereas, since 1968, the Society has supported federal minimum stadards of not less than two years of education for operators of medical equipment emitting radiation; and

Whereas, the Society is convened in Washington, D.C., June 17–23, 1977, and believes it appropriate to express concern about unnecessary radiation exposure to patients caused by operators of equipment who have less than the established educational standards; therefore,

Be it resolved: That The American Society of Radiologic Technologists continues its pursuit for the enactment of federal minimum standards of education for radiologic technologists; and

Be it further resolved: That the members of this Society go on record in support of H.R. 4573, as introduced in the ninety-fifth Congress by the Honorable Edward I. Koch (N.Y.).

[The following information was subsequently received for the record:]

THE AMERICAN SOCIETY OF RADIOLOGIC TECHNOLOGISTS,
Milwaukee, Wis., September 13, 1977.

Hon WARREN G. MAGNUSON,
Chairman, Committee on Commerce, Science, and Transportation,
Russell Senate Office Building, Washington, D.C.

DEAR SENATOR MAGNUSON: Thank you for the opportunity to comment further on the question of radiation health and safety. We offer the following responses to your questions:

Question. "We are told that 50 percent of the operators of radiologic equipment in this country do not meet your society's educational standards. Where are such people generally employed? Do major hospitals usually accept these relatively untrained technicians, even in states without licensing requirements? Or are they primarily hired by private practitioners? Do you have any idea of how many patients are treated by trained technicians versus the number exposed to untrained?"

Answer. The approximately 50 percent of the operators of radiologic equipment who do not meet standards espoused by our Society are employed, for the most part, in offices and clinics of physicians, podiatrists, or chiropractors. A few of them still work in hospitals simply because they have worked there for years, but very few, if any, hospitals now hire unqualified operators.

In the office or clinic, the operator of the radiologic equipment is frequently the receptionist, nurse, secretary, file clerk, or (in one outstanding example I heard of) the maintenance man. The "training" these people receive is frequently a few minutes of instruction by the employer on how to turn on the machine and which button to push. Since most medical school curricula do not include courses in the interpretation of radiographs, in radiation safety, or in radiation biology, many of the employers themselves have had little education specifically directed toward the safe use of radiographic procedures, thus are unable to pass along this kind of information to their employees.

We have no accurate figures on the number of patients exposed to radiation by qualified versus unqualified operators. However, it is apparent that there are more pieces of X-ray equipment in private offices and clinics than in hospitals. Thus, while each operator in a private office or clinic may expose fewer patients to radiation, the total number exposed by unqualified operators may approach, or even exceed, the total number exposed by qualified operators. Moreover, the radiation per exposure given to the patient by the unqualified operator is likely to exceed that given by the qualified operator because the unqualified operator may lack knowledge of radiation safety. Finally, the unqualified operator may need to make several exposures before achieving a satisfactory radiograph, again delivering unnecessary radiation to the patient.

Question. "Another problem in the ionizing area is physicians' prescribing of unnecessary X-ray examinations because of the current malpractice climate. We have heard of studies which may help alleviate this problem, such as a study at the University of Washington to determine the criteria for the most efficacious skull X-rays. Can you see any other routes, legislative or otherwise, for correcting this problem?"

Answer. I feel there may be some value in setting a legal limit on the size of malpractice settlements, although I recognize that such legislation may not be possible or desirable from your standpoint. Any legislation which would attempt to define criteria by which X-ray examinations are ordered would infringe upon the medical judgment of the physician. The current malpractice situation, and the resultant increase in radiographic examinations, again emphasize the need for radiologic technologists who can meet minimum standards of education as would be required by The Radiation Health and Safety bills now before both Houses of Congress.

Question. "On page 2 of your prepared comments you state 'we are satisfied that the implementation of any recommendations with reference to credentialling health manpower will be a very lengthy, time-consuming process.' Exactly how long do you envisage, and what factors are likely to be most responsible for any delay?"

Answer. It has been six years since the Department of Health, Education, and Welfare requested the moratorium on the licensing of additional allied health personnel. Since that time, DHEW has been preoccupied with standards for equipment and has virtually ignored the question of standards for the operators of that equipment. Because of this attitude on the part of DHEW, we have no idea how long it may take before credentialling of radiographic equipment operators will be mandated.

The bills before Congress (S-1695 and HR-4573) both provide a year for the Secretary of HEW to develop standards for the licensing of technologists and the accreditation of educational institutions teaching radiologic technology. The bills further provide for a two year period for the states to enact legislation to meet the standards. On the assumption that a "grandfather clause" will be written into any licensing legislation, we expect a minimum of six years before all operators of X-ray equipment will be required to demonstrate qualifications. Any delay in the passage of this legislation will further delay assurance to the patient that his radiographic examination will be conducted by a qualified operator.

Question. "It is our understanding that no authority exists at the present time for regulation of in-use medical and dental X-ray equipment. Is this correct, and if so, is there a need for further regulatory authority in this area? What factors would limit enforcement of such regulations? Do you think that this should be done by the Federal government, or will an attitude of medical self-policing be adequate?"

Answer. The Bureau of Radiological Health and the various states have some regulations concerning in-use X-ray equipment. These regulations relate primarily to the electrical, mechanical, and radiation safety of the equipment, and not to the actual usage of the equipment. Enforcement of these regulations is difficult because of budgetary restraints, manpower, and the large number of radiographic installations. Self-policing is an impractical answer since many of the owners of the equipment are unaware of the problems with radiation exposure and radiation safety.

With insufficient enforcement of present regulations, it would not seem practical to suggest additional regulations. However, some of the items that might be considered include requirements for proper collimation of the primary beam, gonadal shielding, the accounting for repeated exposures, and again, proper education for the operators of the equipment. These should all be adopted on the national level for the sake of uniformity across the country.

Question. "How serious is the problem of radiation exposure of radiologic technologists? To what extent are such persons being routinely monitored for cumulative radiation exposure, and do programs exist for long-term study of health effects in such individuals?"

Answer. I do not believe there is a serious problem of radiation exposure for registered radiologic technologists, since radiation safety is an important part of the curriculum in any approved educational program for technologists.

In spite of OSHA regulations and the various state radiation protection codes, there may be a problem with over-exposure among some of the non-qualified operators due to ignorance of the regulations and the dangers of excess radiation.

I am not aware of any long-term studies now underway to determine the effect of radiation exposure on operators of radiologic equipment.

Again, thank you for the opportunity to comment further on this question.

Sincerely,

RICHARD G. BAUER, R.T. (ASRT),
President.

Senator STEVENSON. Before we adjourn, a brief statement about our plans might be in order. We have accumulated a great deal of testimony. The committee has also received responses from about 30 Federal agencies concerning their programs and policies with regard to ionizing and nonionizing radiation.

The staff will require several weeks to evaluate all of this evidence. Where it appears the Federal agencies are not carrying out their statutory responsibilities satisfactorily, the committee will communicate its findings to the respective agencies. At that time we will announce additional hearings to receive testimony from the agencies on how these inadequacies are being corrected. If discrepancies or contradictions are evident in the testimony, or the committee receives additional material that casts doubt on the testimony we have received, we will recall witnesses to examine such unresolved matters.

We may in the near future have legislative recommendations to make, including, for example, a mandated study of nonionizing radiation with appropriate funding to be conducted by the National Academy.

I am deeply concerned because of what I have heard about the dangers of radiation of all kinds and what appears to be a fragmentary, at best, research effort in nonionizing radiation, a seriously deficient regulatory and enforcement program to protect citizens from all forms of radiation, and the failure to focus research on future emerging problems such as the shift to coal as a source of energy.

These hearings are just the first round of what will be a continuing serious effort by the committee to face up to radiation and all of its consequences and to protect the public.

The hearing is adjourned.

[Whereupon, at 12:52 p.m., the hearing was adjourned.]

ADDITIONAL ARTICLES, LETTERS, AND STATEMENTS

Prior to the hearings the committee sent the following request for information to Federal agencies having research or regulatory responsibilities related to radiation health and safety.

MAY 19, 1977.

DEAR ————:

Since the enactment of the Radiation Control for Health and Safety Act of 1968 (P.L. 90–602), radiation health and safety research and regulation and other associated federal responsibilities have undergone a profound evoluation. In order to examine this area of significant secientific and public concern, the Senate Committee on Commerce, Science and Transportation is planning comprehensive hearings in June to review and evaluate federal radiation research and regulatory programs.

In order that these programs can be readily compared and evaluated, we are requesting that the various federal agencies carrying out radiation regulation or research provide a comprehensive listing and short description of each of their relevant projects or programs utilizing the format of the two enclosed matrices.

If the format of either of the matrices needs to be modified in order to more adequately describe the nature of certain of your programs, we would appreciate it if you would contact Sharon Nelson (224–0411) or Dan Jaffe (224–9345) of the staff of the Senate Commerce, Science and Transportation Committee in order to discuss such alteration and to assure that the information provided will be in a form that maximizes comparability and ease of evaluation.

In addition, we request your written response to the following questions:

(1) What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e. inception of new agencies, transfers of regulatory authority, etc.)? Now how have these changes affected your overall efforts in the radiation area?

(2) Would you please describe the nature of the contacts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and federal agencies?

(3) Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

(4) What is your reaction to the proposals to consolidate all federal radiation activities into one federal radiation agency?

If you have any other questions concerning this matter, please contact Sharon Nelson or Dan Jaffe of the Committee staff. Your written response to all the above requests should be provided to the Committee no later than June 6.

Sincerely yours,

ADLAI E. STEVENSON,
Chairman, Science, Technology and Space Subcommittee.
WENDELL H. FORD,
Chairman, Consumer Subcommittee.

IONIZING RADIATION

Senator STEVENSON. Mr. Chris Dodge, of the Congressional Research Service, Library of Congress, completed the following charts which provide a rough indication of the categories in which Federal research, regulatory, and development programs fall.

GENERAL OVERLAP OF FEDERAL RESEARCH, REGULATORY, AND DEVELOPMENT—PROGRAMS CONCERNED WITH NONIONIZING RADIATION

Year	1	2	3	4	5	6	7	8	9	10	11
1968	Navy, AF, NIH, ARPA, Army.	Navy	AF, Army	NIOSH, AF, FCC, Army, OTP.	AF	FAA, NIOSH, AF, NIH, Army.	NIH, Army		Navy	Navy, AF, Army	NBS, Army.

The responses received from the Federal agencies follow:

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE,
FOOD AND DRUG ADMINISTRATION,
Rockville, Md., June 8, 1977.

Hon. WENDELL H. FORD,
Chairman, Subcommittee on Consumer, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR SENATOR FORD: This is in reply to your letter of May 19, 1977, in which you request information on our radiation health program for use in your Subcommittee's upcoming hearings on Federal radiation health research and regulation.

Enclosed are answers to the four specific questions contained in your letter. These questions concern radiation and our administration of the Radiation Control for Health and Safety Act of 1968 (Public Law 90-602). In addition, we have enclosed project funding allocation information for radiation programs which cover 1973 to present.

As discussed with the Subcommittee staff, we have not finished the matrices on ionizing and nonionizing radiation. These will be forwarded to you within the next few days.

Sincerely yours,

DONALD KENNEDY,
Commissioner of Food and Drugs.

Enclosures.

Question 1. What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Answer. The regulatory authority of the Food and Drug Administration's Bureau of Radiological Health began with passage of the Radiation Control for Health and Safety Act of 1968, when the Bureau was a unit of the no longer extant Environmental Control Administration. The President's Reorganization Plan No. 3 of 1970 established the Environmental Protection Agency and transferred out of the Bureau of Radiological Health into EPA (which was created by the plan) all of the former's environmental radiation functions. The BRH functions specifically cited by Plan No. 3 as remaining with BRH included such responsibilities as "regulation of radiation from consumer products"; "radiation as used in the healing arts"; and "research, technical assistance, and training" as they related to the Bureau's basic functions.

The Reorganization Plan No. 3 also cited "occupational exposures to radiation" as a function to remain with the Bureau. Over the years, the Bureau has cooperated with the National Institute of Occupational Safety and Health and the Labor Department's Occupational Safety and Health Administration, the two agencies at the Federal level which have lead responsibilities in the area of occupational health.

The overall effect of the foregoing changes was to place greater emphasis upon the Bureau's responsibility for setting and enforcing equipment performance standards for certain consumer goods, for equipment used in the healing arts, equipment used in commercial and industrial settings (including airport baggage inspection units), and the development of a strong, non-regulatory capacity in the field of use and user controls, equipment user training programs (especially for operators of diagnostic X-ray equipment), and the publication of operator instructions, guidelines, and recommendations concerning correct methods of application of diagnostic radiation (X-radiation during pregnancy, gonad shielding, X-ray use for screening purposes). In other words, the changes that have taken place in the Bureau's program orientation have served to sharpen rather than lessen specific Bureau concerns for protecting the public health from equipment-produced radiation.

At the same time, despite the fact that the Bureau does not have regulatory authority for the control and use of naturally occurring and accelerator-produced radioactive materials, the Bureau has maintained a relatively small but effective program in this area. This has been done under the Bureau mandate to reduce unnecessary or unproductive exposure to all radiation. In this connection, the Bureau has maintained a strong support capacity in the field of nuclear medicine and radiopharmaceuticals.

Incorporation into the FDA has had only positive effects upon the Bureau's overall efforts in standards-setting, guideline development, surveillance and monitoring, and oversight and auditing of manufacturers' corrective action programs to bring products into compliance with an applicable standard, and/or to correct a defect (applicable to electronic products manufactured on or after October 1968, date of passage of the Radiation Control for Health and Safety Act of 1968, but prior to promulgation of an applicable performance standard.)

Question 2. Would you please describe the nature of the contacts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and federal agencies?

Answer. Throughout almost all the operating history of the Food and Drug Administration's Bureau of Radiological Health, the Bureau has developed and maintained a close working relationship with State radiological health programs. During the years 1959 through 1977, the Bureau and/or its predecessor agency provided State radiation programs with manpower support through the assignment of personnel. (This included State assignees [full-time professional radiological health personnel] and Commissioned Officer Student Training and Extern Programs.) Through 1977, there will have been 248 assignees (including one scheduled in 1977) and 141 students. During the years 1963 through 1967, the Bureau provided "formula" grants to States in support of their radiological health programs. Total funds involved in the five years amounted to $9,649,200.

In a number of situations, these State assignees returned to the Bureau, bringing back an understanding of State radiation control program problems which helped the Bureau further improve its relations with the States. One principal result was continued support and involvement of the State programs in the Bureau's development of an effective nationwide radiation protection program at all levels.

Section 360(e) of the Radiation Control Act provides that the Bureau may accept enforcement support from State radiation program agencies. As an example of how this authority has been implemented, the Bureau developed contracts with States in FY 75 to assist in the enforcement of the Federal performance standard for diagnostic X-ray equipment. These contracts call for the inspection of certified X-ray systems and providing to the Bureau compliance data based on the inspection of newly certified diagnostic X-ray systems to assure that the requirements of the performance standard are being met. States that participate under these contracts also supplement the amount of information obtained by field components of FDA. Currently, in FY 77, there are contracts with 18 States, with a funding level of approximately $310,000.

Under provisions of the Radiation Control for Health and Safety Act, the Bureau is to "maintain liaison with and receive information from other Federal and State departments and agencies with related interests . . . etc. . . ." (Sec. 356(a)(3)). Largely, however, continuing program activities developed by the Bureau are carried out in conjunction with State radiation protection agencies on a voluntary basis.

The Nationwide Evaluation of X-Ray Trends, known by the acronym NEXT, is an example of a Bureau cooperative effort with the States. It is designed to collect data on exposure and other parameters associated with radiographic procedures through on-site surveys of X-ray installations.

Additionally, programs such as BENT (Breast Exposure: Nationwide Trends), a quality assurance effort to improve techniques employed during mammography, and DENT (Dental Exposure Normalization Technique), an older and conceptually parallel program, further illustrate activities currently conducted jointly by the BRH and State radiation protection agencies. DENT is presently used by 36 Federal, State, and local radiation control agencies, involving an estimated two-thirds of the dental machines in the U.S. Both BENT and DENT utilize efficient methodologies to locate high and low exposure facilities and link an educational aspect to help effect reductions in unnecessary patient exposure.

NEXT, in 1976, involved 43 State or local radiological health programs as well as seven Federal agencies. BENT currently has provided operational training to staff of 13 State agencies and will add at least another four by the end of FY 77. This is in addition to an original five pilot State programs. The National Cancer Institute has provided support to BENT through a $300.000 grant over the next two years. This will enable participation of additional State agencies in the program. In an effort to broaden the conceptual quality assurance ideas embodied in DENT and BENT, the Bureau is presently working with a task force of State representatives to develop a methodology for an action program designed to improve diagnostic image quality and reduce patient exposture. The methodology, originally pilot-tested in West Virginia, will include a testing aspect to identify problem areas and an educational aspect to help facilities institute quality assurance programs on their own. The DENT program is, or has been, active in 37 States.

The Conference of Radiation Control Program Directors, which consists of heads of all State and municipal radiation control programs, as well as from D.C., Puerto Rico, the Virgin Islands, is a corporate body which came into existence about ten years ago with the active support of the Bureau. Annual national meetings of the Conference are jointly supported by the Conference, itself, by the FDA, NRC, and EPA.

To a lesser degree, but wherever the opportunity presents itself, the Bureau either has contracts with or agreements for expanding and developing surveillance methodologies, compliance instrumentation research, standards and guidelines development with such Federal agencies as the National Bureau of Standards (equipment development) and the National Institute of Occupational Safety and Health (NIOSH), the Occupational Safety and Health Administration (OSHA), the Nuclear Regulatory Commission (NRC), the Consumer Product Safety Commission, to name a few examples.

Additional evidence indicative of Bureau-State activity in radiation protection is the relationship demonstrated in the joint development of model State regulations. These regulations are based upon counterpart Federal regulations and standards, and designed to fit the needs of the States for incorporating in whole or part into respective State regulations. Over 40 States have developed comprehensive radiation control regulations based on the use of this model.

There is no basic confusion on the Bureau's part concerning the respective responsibilities of State and Federal agencies, speaking with respect to all State agencies and most Federal agencies. The exception to this is FDA's relationship with EPA in the field of radiation protection. The FDA's position is based upon a number of factors: in particular, the President's Reorganization Plan No. 3 of 1970 in which it is stated that "radiation as used in the healing arts" is a function to be carried out by the Bureau of Radiological Health. In its interpretation of the responsibilities of the now defunct Federal Radiation Council, the EPA has claimed a role at the Federal level for the development of guidelines and standards for "radiation as used in the healing arts." Commissioner Kennedy and EPA Administrator Douglas Costle have begun discussions to resolve this and other matters requiring close coordination and cooperation between the two agencies.

The Federal-State relationship with respect to the Federal radiation control programs is defined in the Radiation Control for Health and Safety Act (Section 360(f)), "Effect on State Standards." No State is permitted to establish, or to continue in effect, any standard which is applicable to the same aspect of performance of such product and which is not identical to the Federal standard.

Question 3. Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved. Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Answer. The question of whether the Food and Drug Administration's radiological health programs could be improved, whether there are deficiencies in operational elements of the FDA radiological health protection programs, and whether present funding levels are adequate—these questions/issues may properly be considered a function of how extensive and in-depth a radiological health program is desired, or is desirable.

A General Accounting Office report, "Radiation Exposure from Diagnostic X-Rays Could Be Reduced," of November 24, 1976, spoke to only one aspect of the Bureau's total radiation-related responsibilities (ionizing radiation). But, in doing so the report, in its second of three recommendations, recommended the allocation to the Bureau of "additional resources" to expedite the review of manufacturers' diagnostic X-ray equipment reports and the inspection of manufacturers."

The report gave no indication of the magnitude of the amount of "additional resources" that it believed would be required.

A Bureau inquiry into the problems associated with the compliance of diagnostic X-ray equipment elicited the information that there is a considerable shortfall in the state of compliance of newly installed diagnostic X-ray equipment.

The average for all manufacturers is about 30 percent, with one manufacturer's equipment showing a 50 percent failure rate with respect to the standard.

A National X-Ray Control System, a Bureau designed proposal to effect a greater degree of conformance to the diagnostic X-ray equipment standard, could cost approximately $70 million over a five-year period.

The National X-Ray Control System (NXCS) is dedicated to dramatically reducing the $2 billion spent each year by the American public for X-rays that have a low probability of affecting patient management. Similarly, ill health resulting from the exposure of these unneeded X-rays, as well as unnecessary exposure due to poor techniques and faulty equipment, is a primary thrust of NXCS. The health care costs resulting from that unnecessary exposure preventable with current technology, exceeds $500 million per year.

The Bureau currently has approximately 18 State radiological health programs under contract (costing approximately $310,000 per year) in order to assure the compliance of newly-installed diagnostic X-ray systems with the diagnostic X-ray equipment performance standard. It is estimated that. in order to do a more effective job of determining compliance with the standard, the Bureau needs the support of the States at a cost of $900,000 per year. It is estimated that $4 million would support an inspection program for all new installations, each of which has the potential for unnecessarily exposing patients.

With respect to whether there are any present deficiencies in the FDA's radiation control program, again it is less a question of deficiency than it is a matter of deciding what other areas related to radiation health and safety one wishes to control. For example, whereby the Radiation Control for Health and Safety Act requires the FDA to conduct and administer an electronic product radiation control program, it only provides authority to mandate and require adherence to equipment performance standards. The manner of use of the equipment, the issues of educational and credentialing requirements for medical radiation technologists (e.g., X-ray technologists), and who should stipulate such requirements (by the States or the Federal government), the effectiveness and safeness of radiation-emitting devices—none of these aspects of health protection is mandated by the Act. The charge to develop user and use guidelines and/or recommendations and the authority to decide about the safeness and effectiveness of equipment, are implied but not provided with regulatory backing by the Act. With respect to guidelines for user training and credentialing, the GAO report mentioned previously recommended establishment of a uniform national credentialing system for medical X-ray personnel.

The guidelines, recommendations, training programs, and State coordinated surveillance and monitoring systems that the FDA has developed and promoted have resulted from the Bureau's moral commitment to reducing unnecessary patient exposure.

Beyond such compliance-related functions lie very important research areas: equipment, instrumentation, and measurements; biologic effects and epidemiology. There are specific modalities such as ultrasound, that would appear to require much more research-developed data than is presently available in the face of the need of the FDA to know more than is currently available about ultrasound. The effects of long-term, low levels of microwave radiation is another area of concern.

Funding for additional research is always an issue with two sides, one that can, perhaps, more appropriately be resolved by an interested and informed third party.

Question 4. What is your reaction to the proposals to consolidate all federal radiation activities into one federal radiation agency?

Answer. The question of consolidating all Federal radiation activities into one agency hinges, in part, on the answer to "How much is too much?" It is possible that such a consolidation proposal would produce a monolithic structure that would be unwieldy, and too cumbersome to react with alacrity to public health and consumer needs, as well as to industry and commercial radiation needs.

Beyond the question of response time lies the issue of response capability. Those with expertise in nuclear matters are not, per se, possessed of expertness in non-ionizing radiation equipment operation. This suggests there may be little if any manpower savings in establishing one overall radiation control Agency. This brings us to what we feel is probably the most important observation to be made about the viableness of a single radiation control agency at the Federal level:

the creation of such an agency would move a significant element of the Federal radiation control effort out of the Federal agency responsible for the health of the population. The regulation of the use of radiation in healing arts, where complex individual and professional judgments are made, requires an agency which can respond specifically to these considerations and which is not encumbered by concerns in other areas.

Use of radiation in the healing arts is somewhat unique in that, of all radiation activities, it is the one which requires the exposure of humans, whether in diagnosis or therapy. Although other Federal radiation control agencies recognize the cost/benefit equation in estimating the degree of permissible radiation exposure, such a balancing of pros and cons is an essential element in the use of radiation in the healing arts.

The consolidation of Federal agencies that are concerned with different applications of radiation within one structure could produce more heat than light, more controversy than solution. Under the circumstances, and in light of the sometimes conflicting justifications in the use of radioactive materials and production of radiation producing equipment (consumer, commercial, medical), one finds no particularly compelling reason for or combining all present Federal agencies that deal with various radiation activities into one unit.

FOOD AND DRUG ADMINISTRATION

RESOURCES FOR RADIOLOGICAL HEALTH PROGRAMS

[Funding allocation in thousands of dollars]

	Fiscal year 1977 estimate	197TQ	Fiscal year 1976	Fiscal year 1975	Fiscal year 1974	Fiscal year 1973
Ionizing radiation products and devices	5,967	2,060	6,815	6,081	5,955	5,35
Ionizing radiation use control	5,416	1,308	4,999	4,461	3,818	2,881

BUDGETED POSITIONS FOR RADIOLOGICAL HEALTH PROGRAMS

	Fiscal year—				
	1977 (estimate)	1976	1975	1974	1973
Ionizing radiation products and devices	181	187	183	173	170
Ionizing radiation use control	130	130	117	101	102
RF-microwave radiation	57	67	76	84	100
Light and sonic radiation	106	82	80	78	64
Total	474	466	456	436	436

Note: A combination of organization and program management system changes in the years prior to fiscal year 1973 prevents our obtaining and presenting comparable financial data for the Bureau. A sequence of changes started in December 1968 (fiscal year 1969) when the National Center for Radiological Health became the Bureau of Radiological Health as a component of the Environmental Control Administration, Consumer Protection and Environmental Health Service. Just 2 yr (fiscal year 1971) later the Bureau was assigned to the Environmental Health Service when it became the successor to the Consumer Protection and Environmental Health Service. 1 yr later (fiscal year 1972) pursuant to Presidential Reorganization Plan No. 3 of 1970 the Bureau was split with components going to EPA and FDA. To further complicate the compilation of comparable data the PMS (program management system) was not established until fiscal year 1973.

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE,
FOOD AND DRUG ADMINISTRATION,
Rockville, Md., June 15, 1977.

Hon. WENDELL H. FORD,
Chairman, Subcommittee on Consumer, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR SENATOR FORD: This is in further reply to your May 19 letter in which you requested information concerning radiation health programs to be used in your Committee's upcoming hearing on Federal radiation health research and regulation.

We are submitting the enclosed document which highlights the Agency's major efforts in the radiological health areas. These are the completed matrices that were enclosed in your May 19 letter. We have provided you earlier with the answers to the four questions contained in that letter.

It should be noted that the format of the matrices has been changed with the permission of your staff. We are enclosing the altered form to clarify for you the correlation between the "matrix column reference" number which appears in the document and the columns in the original matrix.

In addition, funding allocation information has been supplied to you earlier with the answers to your May 19 letter.

If you have any questions please contact me or Mr. Banks of my staff at 443-3793.

Sincerely yours,

ROBERT C. WETHERELL, Jr.,
Director, Office of Legislative Services.

Enclosures.

A SUMMARY OF
THE FOOD AND DRUG ADMINISTRATION'S
RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1978

Activity	Program Area (see legend below)	Matrix Column Reference
1. Issuance of proposed amendments to the diagnostic x-ray equipment performance standard for computed tomography (CT) systems.	II-C	2
2. Continuation of enforcement programs for TV receivers, cold-cathode gas discharge tubes, cabinet x-ray and diagnostic x-ray systems.	II-C	3
3. Contract with twenty States for inspection of diagnostic x-ray systems.	II-C	3
4. Issue mercury vapor lamp standard as a final rule.	III-C	2
5. Issue sunlamp standard as a final rule.	III-C	2
6. Continuation of enforcement program for laser products.	III-C	3
7. Propose amendments to the laser performance standard.	III-C	2
8. Develop enforcement programs for sunlamps and mercury vapor lamps.	III-C	3
9. Develop enforcement program for ultrasound therapy products.	III-C	3
10. Issue microwave diathermy standard as a proposed rule.	IV-C	2
11. Continuation of enforcement program for microwave ovens.	IV-C	3

Activity	Program Area (see legend below)	Matrix Column Reference
12. Continue developmental work on policy statement on utilization of intensifying screens.	II-B	6
13. Evaluate feasibility of general patient exposure limits using in-house organ dose analysis scheme.	II-B	6
14. Develop measurement protocols, test instrumentation and test methods for dose and image performance of computed tomography (CT) systems.	II-B	6
15. Intensify study of diagnostic information per unit dose and alternate concept standard.	II-B	6
16. Complete work on mammographic technique/exposure survey.	II-B	6
17. Initiate a laboratory clinical study to evaluate the relationship between physical parameters and diagnostic mammography and image receptor systems.	II-B	6
18. Design and conduct a pilot program to assess the procedures to be used in a nationwide program to survey medical accelerator exposures/doses in radiation therapy.	II-B	6
19. Design and conduct a technical survey of CRT and CRT devices to clarify and document x-ray exposures associated with such devices.	II-B	6
20. Expand in-house field measurement capability in the UV-Visible-IR region through a variety of instrument procurements, traceability programs for measurement standards, and instrument inter-comparisons.	III-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
21. Continue evaluation of consumer and medical noncoherent sources by extension of the present light sources measurement contract and associated product evaluation activities.	III-B	6
22. Investigate the feasibility of a light measurement assurance program.	III-B	6
23. Intensify evaluations of the performance of diagnostic ultrasonic devices from the standpoint of acoustic output and imaging characteristics.	III-B	6
24. Relate acoustic exposure levels and imaging performance of diagnostic ultrasound devices to risk/benefit analyses of this modality.	III-B	6
25. Design quality assurance test devices and procedures for the masurement and evaluation of acoustic output and imaging capability.	III-B	6
26. Develop compliance test methods and field instrumentation for microwave diathermy.	IV-B	6
27. Develop a collaborative effort with NCI on microwave cancer therapy.	IV-B	6
28. Conduct a clinical survey of microwave levels in hyperthemia treatment.	IV-B	6
29. Develop safety procedures for microwave cancer therapy operating personnel and patients.	IV-B	6
30. Develop plan to reduce exposure to RF sealers.	IV-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
31. Develop voluntary recommendations on the subjects of dental post-operative x rays, dental quality assurance procedures, and guidelines on patient exposure from specific x-ray examinations.	I-D	6
32. Produce audiovisual packages to teach consumer groups about protection against products which emit ratiation.	I-D	6
33. Complete part six of the multi-media packaged training series for x-ray technologists, covering quality assurance x-ray film processor procedures.	I-D	6
34. Administer on a nationwide basis a self-assessment test for x-ray technologists to aid in their continuing education.	I-D	6
35. Conduct a national survey to determine the environmental factors which affect the performance of x-ray machine operators.	I-B	6
36. Conduct a nationwide FDA/State program to identify those x-ray facilities delivering excessive patient exposure during mammography and to perform corrective consultation.	I-F	6
37. Develop performance parameters for scintillation cameras.	I-F	6
38. Develop quality control procedures for rectilinear scanners, dose calibrators, and radiopharmaceutical preparation.	I-D	6
39. Continuation of the nuclear medicine information system.	I-D	6
40. Initiation of a survey of medical accelerator units.	I-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
41. Develop guidelines and recommendations on quality control procedures for tele-therapy and accelerator-therapy units.	I-B	6
42. Continuation of disposal services for radium sources.	I-F	6
43. Continuation of the assessment of effects of low-level ionizing radiation exposure.	II-A	1
44. Continuation of the assessment of in-utero exposure to ionizing radiation.	II-A	1
45. Continuation of the assessment of the delayed effects of I^{131}.	II-A	1
46. Continuation of the assessment of the effects of low energy x rays.	II-A	1
47. Continuation of the assessment of the effects of light exposure.	III-A	1
48. Continuation of the assessment of vision and visual function.	III-A	1
49. Identification and assessment of the effects of ultrasound.	III-A	1
50. Assessment of heating in dental ultrasound.	III-A	1
51. Continuation of the study of effects of low levels of microwave radiation including repetitive pulses and chronic exposures.	IV-A	1
52. Identification and study of microwave induced diseases.	IV-A	1

A SUMMARY OF
THE FOOD AND DRUG ADMINISTRATION'S
RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1977

Activity	Program Area (see legend below)	Matrix Column Reference
1. Publication of a Notice of Intent to propose rules for ionizing radiation therapy equipment.	II-C	2
2. Continuation of enforcement programs for TV receivers, cold cathode gas discharge tubes, and diagnostic x-ray equipment systems.	II-C	3
3. Contracted with eighteen States for inspections of diagnostic x-ray systems.	II-C	3
4. Preparation of a final rule for an ultrasound therapy performance standard.	III-C	2
5. Preparation of a proposed performance standard for mercury vapor lamps.	III-C	2
6. Preparation of a proposed performance standard for sunlamps.	III-C	2
7. Continuation of laser products enforcement program.	III-C	3
8. Developmental work toward performance standard for microwave diathermy equipment.	IV-C	2
9. Continuation of microwave oven enforcement program.	IV-C	3
10. Development of a radiation impact rating index for medical x-ray procedures based on appropriate weighting of all important organ doses.	II-B	6
11. Development of an appropriate application and evaluation procedure for use in association with the NEXT system.	II-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
12. Provide organ dose estimates for Agency environmental assessment reports.	II-B	6
13. Development of handbooks on organ doses for various medical x-ray and fluoroscopic examinations.	II-D	6
14. Application of accumulated organ dose data to various national and international organization dose estimation projects.	II-B	6
15. Publication of accurate measurements of x-ray primary beam exposure rates typical of diagnostic x-ray equipment.	II-B	6
16. Continuation of the development and evaluation of instrumentation and procedures for effective enforcement of all ionizing radiation defect and compliance actions.	II-B	6
17. Quantitation of patient dose data resulting from CT scanner examinations as a function of image content.	II-B	6
18. Development of methods to minimize the radiation exposure associated with mammography while retaining desired diagnostic information.	II-B	6
19. Continuation of the development of methods and devices to be used in evaluating the performance characteristics of diagnostic x-ray systems and related equipment.	II-B	6
20. Continuation and expansion of calibration facilities to support compliance and non-regulatory activities.	II-B	6
21. Evaluation of image receptor performance and the relationship between image quality and exposure.	II-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
22. Continuation of the development of instruments, calibration standards, and methods to support biological research, compliance programs, and light hazards analysis for UV, visible, and infrared radiation sources.	III-B	6
23. Establishment of a standards calibration facility and protocols and techniques to support bioeffects research and compliance programs for ultrasonic sources.	III-B	6
24. Evaluation of medical diagnostic ultrasonic equipment to develop documentation for the parameters which should be specified in an ultrasonic diagnostic equipment performance standard.	III-B	6
25. Implementation of product investigations for sources of noncoherent radiation.	II-B	6
26. Development of reliable field measurement capabilities, including techniques, instrumentation, and the calibration for both research and routine application needs for RF and microwave sources.	IV-B	6
27. Establishment of test methodologies and selection of instruments to provide compliance testing capabilities for microwave diathermy.	IV-B	6
28. Development of new diathermy applicators which will meet proposed leakage requirements of the diathermy standard while providing satisfactory clinical performance.	IV-B	6
29. Evaluation of citizens band radio to establish acute hazards associated with the use of hand-held and mobile units.	IV-B	6
30. Preparation of a technical overview on medical x rays during pregnancy.	I-D	6

Activity	Program Area (see legend below)	Matrix Column Reference
31. Implementation of a consumer education program in the medical and consumer radiation program.	I-D	6
32. Completion of a study on the effectiveness of selective criteria for ordering of skull x rays following trauma.	I-D	6
33. Marketed parts four and five of the packaged training series for x-ray technologists.	I-D	6
34. Initiation of the development of voluntary medical radiation recommendations concerning x rays during pregnancy and quality assurance programs for diagnostic medical x-ray facilities.	I-D	6
35. Publication of a catalog of available x-ray quality assurance tools and techniques.	I-D	6
36. Continuation and expansion of quality assurance (BENT) program for mammography facilities.	I-D	6
37. Development of a whole body scanner for determination of biological distribution of radiopharmaceuticals in patients.	II-B	6
38. Implementation of guidelines for the quality assurance testing of scintillation cameras used in nuclear medicine.	II-D	6
39. Development of uniform criteria for the evaluation of products containing naturally-occurring or accelerator-produced radioactive materials via a Federal/State task force.	II-E	6
40. Evaluation of Co^{60} teletherapy units in cancer treatment facilities to determine accuracy and precision with which a specified dose of radiation is delivered.	II-B	6
41. Consumer product radiation symposium conducted.	II-D	6
42. Preparation of a mathematical model to assess risks and benefits of mammography.	II-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
43. Refine and test biophysical dosimetry model in study of radiation-induced developmental anomalies.	II-A	1
44. Continuation of the study on effects of ionizing radiation on selected processes of development.	II-A	1
45. Investigate dose responses of thyroid from I^{131} and localized thyroid and pituitary x-irradiation in rats.	II-A	1
46. Study of cytogenic and teratogenic effects following x-ray exposure.	II-A	1
47. Analyze somatic chromosome aberration of x-rayed embryonic cells.	II-A	1
48. Study of breast cancer and other malignancies following multiple fluoroscopies.	II-A	1
49. Study of diagnostic I^{131} exposure in children.	II-A	1
50. Study of thyroid tumor risk from scalp x-irradiation during childhood.	II-A	1
51. Continuation of a followup study of persons treated for thyrotoxicosis.	II-A	1
52. Conduct of an analysis of the critical issues of diagnostic ultrasound.	III-A	1
53. Followup study of children exposed in-utero to ultrasound.	III-A	1
54. Study of visual function and pathology from light stress.	III-A	1
55. Study of light-induced mutagenesis.	III-A	1
56. Study of enhancement of viral infections by light.	III-A	1
57. Study of hyperbilirubinemia and visual damage following light exposure.	III-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
58. Development of UV exposure recommendation.	III-A	1
59. Update review of risks and benefits of photodynamic therapy for herpes simplex infections.	III-A	1
60. Continuation of the study on effects of occupational exposure to radar.	IV-A	1
61. Continuation of the study on effects on offspring of men exposed to radar.	IV-A	1

A SUMMARY OF
THE FOOD AND DRUG ADMINISTRATION'S
RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1976

Activity	Program Area (see legend below)	Matrix Column Reference
1. Publication of Notice of Intent to propose rules for computed tomograph (CT) systems.	II-C	2
2. Continuation of cabinet x-ray, diagnostic x-ray systems, TV receiver, and cold-cathode gas discharge tube enforcement programs.	II-C	3
3. Contracted with eighteen States for inspection of diagnostic x-ray systems.	II-C	3
4. Publication of proposed ultrasound therapy standard.	III-C	2
5. Publication of proposed criteria for mercury vapor lamps.	III-C	2
6. Developmental work for sunlamp performance standard.	III-C	2
7. Initiation of an enforcement program for laser performance standard.	III-C	3
8. Developmental work for microwave diathermy equipment.	IV-C	2
9. Continuation of microwave oven enforcement program.	IV-C	3
10. Development of a system for estimating organ doses as a function of the physical parameters used during radiology procedures.	II-B	6
11. Installation of an automated system for calibrating and maintaining records of x-ray survey instruments.	II-F	6

Activity	Program Area (see legend below)	Matrix Column Reference
12. Establishment of a "guide number" for determining and providing illumination levels for various light sources without exceeding a specified UV exposure limit.	III-B	6
13. Transfer power meter made available to laser manufacturers.	III-F	6
14. Contracted to characterize and measure radiation emission levels from various illumination sources.	III-B	6
15. Survey initiated to evaluate the performance and use of diagnostic ultrasound equipment in 50 U.S. facilities.	III-B	6
16. Development of portable ultrasound measurement device under contract.	III-B	6
17. Development of a computer program based on a mathematical theory which predicts absorbed power density (of microwave radiation) at any point inside an exposed body.	IV-B	6
18. Development of a miniature microwave field probe and optical telemetry system.	IV-B	6
19. Study of the range and magnitude of microwave radiation exposure associated with marine radar units.	IV-B	6
20. Establishment of a formal system using the FEDERAL REGISTER to issue voluntary medical radiation recommendations, defining and delineating good radiation protection practices.	II-D	6
21. Mailed gonad shielding literature to all U.S. radiologists.	II-D	6
22. Conducted a national conference on the quality assurance aspects of film and screen selection in diagnostic radiology.	II-D	6

Activity	Program Area (see legend below)	Matrix Column Reference
23. Production of a film on radiation protection in the field of industrial x ray which subsequently won a national award.	II-D	6
24. The Dental Exposure Normalization Technique was expanded to twenty-nine State agencies.	II-F	6
25. Performed a pilot study to determine the environmental factors which affect the performance of medical x-ray technologists.	II-B	6
26. Initiation of an FDA/State program to identify those x-ray facilities delivering excessive patient exposure during mammography and to perform corrective consultation.	II-F	6
27. Development of a series of training workshops on quality assurance in nuclear medicine for nuclear medicine technologists.	II-D	6
28. Establishment of an intramural task force on short-lived radionuclides for medical applications.	II-F	6
29. Conducted radiopharmaceutical dosimetry symposium.	II-D	6
30. Development of performance criteria for personnel monitoring.	II-F	6
31. Study of effects of ionizing radiation on fetal growth and biochemical development.	II-A	1
32. Study of biological processes correlated with delayed radiation diseases.	II-A	1
33. Continuation and expansion of Oxford survey of childhood cancers.	II-A	1
34. Study of thyroid tumor risk from scalp x-irradiation during childhood.	II-A	1
35. Creation of intramural task force for biological basis for x rays during pregnancy.	II-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
36. Development of a biological basis for justification of gonad shielding recommendation.	II-A	1
37. Analyze data related to phototherapy - neurotoxicity of hyperbilirubinemia in newborn.	III-A	1
38. Study of enhancement of viral infections by light.	III-A	1
39. Study of visual function and pathology from light stress.	III-A	1
40. Study of light-induced mutagenesis.	III-A	1
41. Evaluation of material relevant to biological effects aspects of laser standard.	III-A	1
42. Development of biological basis for sunlamp standard.	III-A	1
43. Development of biological basis for Agency action with Nuva-Lite.	III-A	1
44. Investigate reported incidents involving mercury vapor lamps and UV dental apparatuses.	III-A	1
45. Continuation of study on occupational exposures to radar.	IV-A	1
46. Study of effects on offspring of men with high level exposure to microwave radiation.	IV-A	1
47. Review of microwave oven exemption.	IV-A	3

A SUMMARY OF THE FOOD AND DRUG ADMINISTRATION'S RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1975

Activity	Program Area (see legend below)	Matrix Column Reference
1. Continuation of cabinet x-ray and diagnostic x-ray systems enforcement programs.	II-C	3
2. Contracted with eighteen States for inspection of certified diagnostic x-ray systems.	II-C	3
3. Continuation of TV receiver and cold-cathode gas discharge tube enforcement programs.	II-C	3
4. Continuation of x-ray equipment assemblers' workshops.	II-D	3
5. Publication of assemblers' guide to diagnostic x-ray systems.	II-D	3
6. Study of the use and design of medical linear accelerators.	II-B	6
7. Publication of final laser preformance standard.	III-C	2
8. Developmental work for ultrasound therapy standard.	III-C	2
9. Developmental work for mercury vapor lamp performance standard.	III-C	2
10. Developmental work for sunlamp performance standard.	III-C	2
11. Publication of Notice of Intent to regulate microwave diathermy equipment.	IV-C	2

Activity	Program Area (see legend below	Matrix Column Reference
12. Continuation of microwave oven enforcement program.	IV-C	3
13. Survey of electron microscopes for for x-ray leakage.	II-C	3
14. Development of light measuring device for diagnostic x-ray systems compliance testing.	II-B	6
15. Patent assigned to compliance test stand for diagnostic x-ray systems.	II-F	6
16. Development of a portable instrument for measuring radiation exposure and exposure time.	II-B	6
17. Final report issued on the nationwide X-Ray Exposure Studies.	II-B	6
18. Completion of physician Radiological Health Sciences Learning Laboratory.	I-D	6
19. Establishment of an accession system to physician Learning Laboratory.	I-D	6
20. Report on the performance of medical x-ray technologists and their contribution to unnecessary patient exposure completed.	I-B	6
21. Provided criteria pertaining to x-ray technologist qualifications to Medicare program.	I-F	3
22. Assistance to Civil Service Commission on x-ray technologist qualifications.	I-F	3
23. Pilot test of quality assurance tools and techniques.	I-D	6
24. Study of radionuclide pollution of the Ohio River. (Joint FDA/EPA Project)	I-B	6
25. Study of efficacy and radiation dose of several radionuclide myocardial imaging agents.	I-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
26. Design of a Computer Assisted Medical Internal Radiation Dosimetry (CAMIRD) system).	I-B	6
27. National conference on I^{123} applications in nuclear medicine.	I-D	6
28. Design of a second generation nuclear medicine reporting and data storage system (NUMEDACON).	I-B	6
29. Testing of laser eyewear.	III-B	6
30. Laser calorimeter system validated using the National Bureau of Standards system.	III-B	6
31. Completion of a system to visualize and measure output characteristics of ultrasound diagnostic devices.	III-B	6
32. Field survey of diagnostic ultrasound equipment.	III-B	6
33. Development of new mathematical techniques and computer programs for demonstrating distribution of RF and microwave energy.	IV-B	6
34. Survey of microwave diathermy units.	IV-B	6
35. Study of chronic radiation effects in dogs.	II-A	1
36. Study of biochemical development as a result of in-utero x-ray exposure.	II-A	1
37. Investigation of processes in x-ray initiation of delayed radiation disease.	II-A	1
38. Study of the promotion of RNA virus leukemia by ionizing radiation.	II-A	1
39. Development of a method to assess degree of somatic risk from partial and whole body irradiation with x-rays.	II-A	1
40. Continuation of Oxford survey of childhood cancers.	II-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
41. Followup study of U.S. Army x-ray technologists to determine overall mortality rates.	II-A	1
42. Continuation of Radiation Registry for Physicians.	II-A	1
43. Study of exposure to I^{131} and development of thyroid neoplasms.	II-A	1
44. Development of guidelines for x-irradiation during pregnancy.	II-F	6
45. Development of guidelines for medical practitioners who use ionizing radiation in the treatment of disease.	II-F	6
46. Hospital surveys of phototherapy and obstetric ultrasound.	III-A	1
47. Study of visual function and pathology from light stress.	III-A	1
48. Study of enhancement of viral infections by light.	III-A	1
49. Study of infrared radiation-induced mutagenesis.	III-A	1
50. Study of ultrasonic effects in reproduction and fetal development.	III-A	1
51. Investigation of the biophysical characterization of ultrasound exposures.	III-A	1
52. Development of biomedical basis for ultrasound therapy standard.	III-A	1
53. Biophysical characterization of microwave exposures of biological specimens.	IV-A	1
54. Study of effect of chronic low-level microwave irradiation on growth, development, protein and energy metabolism in rats.	IV-A	1
55. Study of animal behavior and neurochemistry of the central nervous system after microwave radiation exposure.	IV-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
56. Study of mutagenic, chromosomal, and reproductive effects of microwaves.	IV-A	1
57. Development of a wavelength apparatus for the study of microwave cataractogenesis.	IV-A	1
58. Study of microwave radiation effects; occupational exposure to radar.	IV-A	1
59. Study of effects of offspring of high level military exposure to microwave radiation.	IV-A	1

A SUMMARY OF THE FOOD AND DRUG ADMINISTRATION'S RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1974

Activity	Program Area (see legend below)	Matrix Column Reference
1. Publication of final cabinet x-ray performance standard.	II-C	2
2. Initiation of enforcement program for diagnostic x-ray systems.	II-C	3
3. Initiation of enforcement program for cabinet x-ray systems.	II-C	3
4. Contracted with seven States for purposes of diagnostic x-ray equipment inspection.	II-C	3
5. Continuation of TV receiver and cold-cathode gas discharge tube enforcement programs.	II-C	3
6. Conducted nationwide workshops for assemblers of diagnostic x-ray systems.	II-D	3
7. Published assembler's guide (handbook) for practitioners.	II-D	3
8. Developmental work for laser performance standard.	III-C	2
9. Developmental work for ultrasound therapy performance standard.	III-C	2
10. Developmental work for sunlamp performance standard.	III-C	2
11. Continuation of microwave oven enforcement program.	IV-C	3
12. Development of a voltage measuring device for testing of diagnostic x-ray equipment.	II-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
13. Development of an environmentally controlled wave-guide irradiation facility to determine integral doses from continuous wave microwave radiation sources.	IV-B	6
14. Completion of a study of the efficacy of x-ray pelvimetry examinations.	I-B	6
15. Development of the 10-day rule for ionizing radiation exposure.	I-B	1
16. Addition of a patient selection document to the physician Radiological Health Sciences Learning Laboratory.	I-D	6
17. Establishment of regional training committees to identify and coordinate State and local radiological health training needs.	I-D	6
18. Collection of the NEXT program's first year of data.	I-F	6
19. Study on cancer therapy by interstitial and intracavitary radiation.	I-B	6
20. International symposium on radiopharmaceuticals.	I-D	6
21. Continuation of Oxford survey of childhood cancers.	II-A	1
22. Continuation of Radiation Registry of Physicians.	II-A	1
23. Social Security Administration disability study.	II-A	1
24. Study on childhood cancer in relation to pre-natal irradiation of U.S. servicemen's dependents.	II-A	1
25. Study of the use of phototherapy for jaundice in newborns.	III-A	1
26. Study of phototherapy and hyperbilirubinemia.	III-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
27. Study of intense light and visual function.	III-A	1
28. Study of cell processes and light.	III-A	1
29. Study of light and activation of latent tumor viruses.	III-A	1
30. Study of light and carcinogenesis in rodents.	III-A	1
31. Study of phototherapy for jaundice of the newborn.	III-A	1
32. Hospital surveys of phototherapy use and obstetric ultrasound.	III-B	1
33. Feasibility study of adverse effects of fetal exposure to ultrasound.	III-A	1
34. Study of embryological effects from ultrasound exposure.	III-A	1
35. Development of automated ultrasonic exposure facility.	III-F	6
36. Study of effects of ultrasound on the clotting mechanisms.	III-A	1
37. Neurobehavioral effects of microwave radiation in primates studies.	IV-A	1
38. Study of developmental effects of microwave radiation.	IV-A	1
39. Study of biophysical characterization of microwave biological effects.	IV-A	1
40. Study of genetic and chromosomal effects of microwave irradiation.	IV-A	1
41. Study of microwave cataractogenesis.	IV-A	1

A SUMMARY OF
THE FOOD AND DRUG ADMINISTRATION'S
RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1973

Activity	Program Area (see legend below)	Matrix Column Reference
1. Publication of proposed cabinet x-ray performance standard.	II-C	2
2. Continuation of TV receiver enforcement program.	II-C	3
3. Continuation of cold-cathode gas discharge tube enforcement program.	II-C	3
4. Developmental work toward laser performance standard.	III-C	2
5. Continuation of microwave oven enforcement program.	IV-C	3
6. Full operation of electrical and ionizing radiation calibration facilities.	II-B	6
7. Issuance of final report on test methods for diagnostic x-ray equipment.	II-B	6
8. Continuation of TV receiver testing.	II-C	3
9. Development of diagnostic x-ray image analysis capacity.	II-B	6
10. Expansion of facilities and capabilities of laser laboratory.	III-B	6
11. Preliminary study of laser safety goggles.	III-B	6
12. Survey of selected facilities concerning use and performance of ultrasonic therapy equipment.	III-B	6
13. Development of a portable ultrasonic radio meter.	III-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
14. Evaluation of new microwave oven leakage detectors.	IV-B	6
15. Completion of data collection on medical products and radiofrequency interference.	IV-B	6
16. Study of external fields around microwave diathermy applicators.	IV-B	6
17. Study of efficacy of x-ray pelvimetry examinations.	I-B	6
18. Initiation of a long-term agreement with the American College of Radiology to sell the physician's Radiological Health Sciences Learning Laboratory.	I-D	6
19. Sale of physician Learning Laboratory to 25 medical schools.	I-D	6
20. Marketed three packaged training programs for x-ray technologists.	I-D	6
21. Conducted a pilot educational/awareness campaign on radiation protection for x-ray technologists.	I-D	6
22. Radiological health training courses for x-ray technologists.	I-D	6
23. Developmental work for the Dental Exposure Normalization Technique (DENT) program completed.	I-D	6
24. Clinical evaluation of Xenon^{133} for performing ventilation and perfusion studies.	I-B	6
25. Study of status and future manpower needs of physicists in medicine in the U.S.	I-B	6
26. Continuation of the Radiation Registry for Physicians.	II-A	1
27. Feasibility study of x-ray induced breast cancer conducted.	II-A	1
28. Oxford survey of childhood cancers performed.	II-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
29. Continuation of cooperative thyrotoxicosis therapy followup study.	II-A	1
30. Continuation of study on effects of fallout on the thyroid gland of children.	II-A	1
31. Continuation of long-term study on effects of radiation exposure to beagles at pre- and post-natal ages.	II-A	1
32. Study of relationship of enzyme activity and protein synthesis changes and morphological changes observed in developing rats.	II-A	1
33. Development of mathematical dose models for estimating bone marrow doses.	II-A	1
34. Study of effects of different (light) radiations on animal-virus mammalian cell inter-actions.	III-A	1
35. Analysis of the relation between intermediate levels of bilirubinemia at birth and mental and physical impairment up through four or more years of age.	III-A	1
36. Hospital survey of phototherapy use.	III-B	1
37. Study of radiation effects on virus mammalian cell interactions.	III-A	1
38. Development of a biological research program directed at hazards relating to ultrasound.	III-A	1
39. Development of an ultrasound exposure laboratory.	III-A	1
40. Continuation of hospital survey of use of diagnostic ultrasound.	III-B	1

Activity	Program Area (see legend below)	Matrix Column Reference
41. Development of a model by which tissue dose can be calculated predictively from the standpoints of known complex dielectric constants of various tissues, volume of tissue and irradiation frequency.	IV-A	1
42. Study of genetic and chromosomal effects of microwave radiation.	IV-A	1
43. Study of microwave cataractogenesis.	IV-A	1
44. Study of biochemical and morphological effects of microwave radiation.	IV-A	1
45. Study of sensory and neurological effects of microwaves.	IV-A	1

A SUMMARY OF THE FOOD AND DRUG ADMINISTRATION'S RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1972

Activity	Program Area (see legend below)	Matrix Column Reference
1. Publication of final diagnostic x-ray equipment performance standard.	II-C	2
2. Developmental work for cabinet x-ray performance standard.	II-C	2
3. Continuation of TV receiver enforcement program.	II-C	3
4. Continuation of cold-cathode gas discharge tube enforcement program.	II-C	3
5. Continuation of microwave oven enforcement program.	IV-C	3
6. Initiation of State assistance in providing microwave oven inspection data to FDA.	IV-C	3
7. Completion of electrical calibration facilities in addition to improved ionizing radiation calibration facilities.	II-B	6
8. Development of instrumentation and apparatus to determine compliance with provisions of the diagnostic x-ray equipment performance standard.	II-B	6
9. Studies of three dental radiographic positioning devices.	II-B	6
10. Studies of x-ray films/screens.	II-B	6
11. Cintinuation of laboratory testing of TV receivers.	II-C	3
12. Life-testing of high voltage rectifiers conducted.	II-C	3

Activity	Program Area (see legend below	Matrix Column Reference
13. Developmental work toward calibration and measurement facilities to determine potential biological hazard (light and sonic radiation)	III-B	6
14. Continuation of portable ultrasonic intensity measurement system evaluations.	III-B	6
15. Work with NBS on improving calibration capabilities to insure greater accuracy for laser and other light measuring instruments.	III-B	6
16. Continuation of microwave oven endurance testing.	IV-C	3
17. Continuation of research on the effects of RF and microwave interference on implanted cardiac pacemakers.	IV-B	6
18. Radiological health training courses.	I-D	6
19. Development of packaged training programs.	I-D	6
20. Field testing of Radiological Health Sciences Learning File for physicians.	I-D	6
21. Development of a prototype male gonad shield.	I-B	6
22. Pilot study of the Nationwide Evaluation of X-Ray Trends (NEXT) program.	I-F	6
23. Development of a Technetium^{99m} macro-aggregated albumin kit.	I-B	6
24. Clinical evaluation of I^{123} for thyroid diagnosis performed.	I-B	6
25. Study of x-ray effects on development and function of central and peripheral nervous systems.	II-A	1
26. Study of effects of pre-natal x-ray exposure.	II-A	1
27. Study of long-term effects of radiation exposures on beagles at different pre- and post-natal ages.	II-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
28. Study of effects of partial body irradiation.	II-A	1
29. Study of radiation-induced cocarcinogenesis.	II-A	1
30. Study of x-ray induced amyloidosis in Chinese hamsters.	II-A	1
31. Study of effects of x rays and UV in animal virus-mammalian cell interactions.	II/III-A	1
32. Development of Social Security Administration Disability standards.	II-A	1
33. Continuation of cooperative thyrotoxicosis therapy followup study.	II-A	1
34. Study of effects of x-ray exposure on the fetus.	II-A	1
35. Study of effects of diagnostic I^{131} in children.	II-A	1
36. Continuation of Radiation Registry of Physicians.	II-A	1
37. Study of the effects of different (light) radiations on animal viruses.	III-A	1
39. Experimental biological research for sonic products and devices.	III-A	1
40. Study of the feasibility to evaluate long-term effects in children of diagnostic use of ultrasound.	III-A	1
41. Hospital survey of use of diagnostic ultrasound.	III-B	1
42. Continuation of the followup study of radar workers.	IV-A	1
43. Continuation of the parental irradiation exposure and Down's Syndrome study.	IV-A	1

A SUMMARY OF
THE FOOD AND DRUG ADMINISTRATION'S
RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1971

Activity	Program Area (see legend below)	Matrix Column Reference
1. Publication of proposed diagnostic x-ray equipment performance standard.	II-C	2
2. Developmental work for cabinet x-ray performance standard.	II-C	2
3. Continuation of TV receiver enforcement program.	II-C	3
4. Initiation of enforcement program for cold-cathode gas discharge tubes.	II-C	3
5. Initiation of a microwave oven enforcement program.	IV-C	3
6. Survey of industrial microwave heating equipment.	IV-C	3
7. Continuation of Bremsstrahlung radiation study to support TV receiver compliance testing.	II-B	6
8. Upgrading of x-ray survey instrument calibration services.	II-F	6
9. Completion of test procedures for compliance testing of diagnostic x-ray equipment.	II-C	6
10. Laboratory tests of TV receivers.	II-C	3
11. Investigation into x-ray emission characteristics of TV tubes.	II-C	3
12. Testing of high voltage vacuum switches.	II-B	6
13. Completion of industrial x-ray equipment testing.	II-C	3

Activity	Program Area (see legend below)	Matrix-Column Reference
14. Developmental work for calibration facility for diagnostic and therapeutic ultrasonic medical equipment.	III-B	6
15. Developmental work for portable ultrasonic intensity measurement systems.	III-B	6
16. Development of a portable laser hazard meter.	III-B	6
17. Development of a scanning instrument for measuring laser characteristics.	III-B	6
18. Continuation of work toward a test procedure to evaluate microwave oven interference with cardiac pacemakers.	IV-B	6
19. Compliance testing of microwave ovens.	IV-C	3
20. Expansion and improvements in endurance testing of microwave ovens.	IV-C	3
21. Radiological health training courses.	I-D	6
22. Development of new training courses in microwave instrumentation and survey techniques, lasers, nuclear medicine, etc.	I, II, IV-D	6
23. Radiological health training courses for chiropractors.	I-D	6
24. Completion of report on the health hazards for radioactive materials not regulated by AEC.	I-B	6
25. Establishment of a nuclear medicine laboratory to evaluate benefit/risk of nuclear medicine procedures.	I-B	6
26. Study of radiation effects of organ systems in larger mammals.	II-A	1
27. Study of in-utero and immunological effects of radiation.	II-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
28. Study of age sensitivity and long-term effects of Sr^{89} in cats.	II-A	1
29. Study of effects of x-irradiation on virus-mammalian cell interactions.	II-A	1
30. Study of mammary tumors: a search for viral etiology and immune suppression by x-radiation.	II-A	1
31. Study of the effects of the fetus of x-ray exposure.	II-A	1
32. Maintenance of the Radiation Registry for Physicians.	II-A	1
33. Continued PHS support of the Atomic Bomb Casualty Commission.	II-A	1
34. Continuation of Utah thyroid disease surveillance study.	II-A	1
35. Study of the effects of radiation in virus mammalian cells interactions.	III-A	1
36. Study on the biological effects of ultrasound.	III-A	1
37. Study conducted to develop instrumentation and methodologies for the determination of microwave exposure and dose distributions in biological materials.	IV-A	1
38. Investigations into microwave thermal distribution in the eye.	IV-A	1
39. Study on the in-utero effects of microwaves.	IV-A	1
40. Study of the molecular effects of microwaves.	IV-A	1
41. Followup study of radar workers.	IV-A	1
42. Continuation of the study on pre-natal radiation and Down's syndrome.	IV-A	1

A SUMMARY OF
THE FOOD AND DRUG ADMINISTRATION'S
RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1970

Activity	Program Area (see legend below)	Matrix Column Reference
1. Publication of cold-cathode gas discharge tube performance standard.	II-C	2
2. Initiation of TV receiver standard enforcement program.	II-C	3
3. Publication of regulations for record-keeping, import requirements, and defective products (ionizing radiation).	II-C	2
4. Publication of regulations for record-keeping, import requirements and defective products (light and sonic radiation).	III-C	2
5. Publication of final microwave oven standard.	IV-C	2
6. Nationwide survey of microwave ovens.	IV-C	3
7. Publication of regulations for record-keeping, import requirements, and defective products (RF microwave).	IV-C	2
8. Study of Bremsstrahlung radiation to support compliance and testing of TV receivers.	II-B	6
9. Adoption of automatic data acquisition system.	II-F	6
10. Laboratory testing of TV receivers.	II-C	3
11. Laboratory testing of TV receiver components.	II-C	3
12. Study of TV projection systems.	II-B	6
13. Development of x-ray detection instrument for TV service technicians.	II-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
14. Establishment of survey instrument calibration protocol.	II-B	6
15. Testing of industrial x-ray equipment.	II-B	6
16. Establishment of facility for calibrating microwave survey instruments.	IV-F	6
17. Development of an inexpensive electronic readout.	IV-B	6
18. Study of characteristics of diode detectors for use in microwave survey instruments.	IV-B	6
19. Development of a testing program to determine the susceptability of cardiac pacemakers to electromagnetic interference.	IV-B	6
20. Survey of microwave ovens from major manufacturers.	IV-C	3
21. Field and laboratory testing of microwave oven leakage radiation.	IV-C	3
22. Evaluation of microwave oven distribution by chemical methods.	IV-B	6
23. Initiation of life-test program for domestic and commercial microwave ovens.	IV-C	3
24. Comparison of several types of microwave radiation survey instruments.	IV-B	6
25. Radiological health training courses.	I-D	6
26. Research studies concerning cyclotron productions of I^{131}.	I-B	6
27. Survey of radionuclide use in medicine.	I-B	6
28. Development of Radiological Health Handbook.	I-D	6
29. Continuation of the cooperative thyrotoxicosis therapy followup study.	II-A	1
30. Study of cellular repair of x-ray damage during the cell cycle.	II-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
31. Virological, hormonal and immunological characterization of radiation-induced mammary tumors.	II-A	1
32. Study of the effect of age or radiation-induced thyroid tumors.	II-A	1
33. Study of effect of immunosuppression on radiation-induced cancer.	II-A	1
34. Study of effects of diagnostic I^{131} in children.	II-A	1
35. Surveillance of children in Utah possibly exposed to I^{131} from weapons testing.	II-A	1
36. Study of fetal irradiation.	II-A	1
37. Study of paternal exposure to radar and Down's Syndrome.	II-A	1
38. Study of mortability and morbidity patterns of patients treated for hyperthyroidism.	II-A	1
39. Study of mental and other effects of scalp x-irradiation for tinea capitis.	II-A	1
40. Establishment of a Radiation Registry for Physicians.	II-A	1
41. Study of effects of UV radiation on viral oncogenic transformation in mammalian cells.	III-A	1
42. Influence of ultrasonic energy on cellular function.	III-A	1
43. Study of the genetic effects of microwave radiation.	IV-A	1
44. Study of the developmental effects of microwaves.	IV-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
45. Study of the biological effects of microwaves.	IV-A	1
46. Study of the neurophysiological effects of microwaves.	IV-A	1

A SUMMARY OF THE FOOD AND DRUG ADMINISTRATION'S RADIATION PROTECTION ACTIVITIES

Fiscal Year: 1969

Activity	Program Area (see legend below)	Matrix Column Reference
1. Survey of major TV manufacturers.	II-C	3
2. Publication of TV receiver performance standard.	II-C	2
3. Developmental work for diagnostic x-ray equipment performance standard.	II-C	2
4. Developmental work for microwave oven performance standard.	IV-C	2
5. Issuance of variances and amendments to equipment performance standards	*	2
6. Annual meetings of FDA/BRH TEPRSSC advisory committee	*	6
7. Upgrade Council of State Governments' regulations.	*	3
8. Recall of defective products not subject to performance standards.	*	3
9. Monitor electronic product imports.	*	3
10. Review of manufacturers' quality control and testing programs.	*	3
11. Development of a TV survey instrument	II-B	6
12. Development of thermoluminescent dosimetry system for accurately and inexpensively measuring integrated ionizing radiation exposure.	II-B	6
13. Development of an x-ray pulse counter to check performance of x-ray machine timers.	II-B	6

Activity	Program Area (see legend below)	Matrix Column Reference
14. Conduct two studies concerning effects of microwave irradiation of selected organic compounds and thermoluminescent dosimetry material for microwave exposure.	IV-B	6
15. Surveys of far-field emissions from microwave ovens.	IV-B	3
16. Design of a prototype laser hazard meter for measurement of continuous-wave low-power lasers.	III-B	6
17. Radiological health training courses.	I-D	6
18. Radiopharmaceutical symposium.	I-D	6
19. Radiology administrator program.	I-D	6
20. Nuclear medicine technologist training program.	I-D	6
21. Development of radioactive materials reference manual.	I-D	6
22. Initiation of nationwide X-ray Exposure Study.	I-B	1
23. Initiation of fetal irradiation study.	II-A	1
24. Study of delayed effects of scalp x irradiation.	II-A	1
25. Study of in-utero irradiation with high and low energy x rays at various dose rates.	II-A	1
26. Study of effects of x irradiations on enzyme induction and protein synthesis.	II-A	1
27. Study of effects of radiation damage to nucleic acids on rat liver cell function.	II-A	1
28. Study of effects of high and low energy x rays on immunocompetence.	II-A	1
29. Study of chromosome stickiness and division delay in x irradiated cultured cells.	II-A	1

Activity	Program Area (see legend below)	Matrix Column Reference
30. PHS support of the Atomic Bomb Casualty Commission.	II-A	1
31. Cooperative thyrotoxicosis therapy followup study.	II-A	1
32. Study of effects of using I^{131} in children.	II-A	1
33. Initiation of a Radiation Incidents Registry.	**	1
34. Study of diagnostic radiation in short-stay general hospitals.	II-B	1
35. Study of light enhancement of tumor virus transformation.	III-A	1
36. Study of influence of ultrasonic energy on cellular function.	III-A	1
37. Study of prenatal radiation exposure and Down's syndrome.	IV-A	1

---

* This activity relates to three FDA program areas: Ionizing Radiation - Products and Devices, Light and Sonic Radiation, and RF Microwave, and should be considered in the category of C (below) - Performance Standards, Compliance and Surveillance, and are carried out on a continuing basis.

** Same as above: this particular activity falls under the category of General Research (B).

ENVIRONMENTAL PROTECTION AGENCY

Radiation Program and Resource Information, June 6, 1977

I. NON-IONIZING RADIATION

A. Studies to determine human health effects

The program resources have been almost exclusively employed to support intramural, interdisciplinary health effects research at Research Triangle Park, North Carolina. The emphasis has been on the development of RF exposure systems of environmental importance, e.g., FM Radio, UHF-TV, radar, and microwave ovens for use in animal and cellular experimentation. The biological parameters which are investigated include teratology, immunology, spontaneous and learned behavior, cytogenetics, reproductive genetics, biochemical and biophysical effects. The subjects of the investigations range from macromolecular, bacterial, and human cell lines to mice, rats, hamsters, dogs and monkeys.

	Fiscal year—						
	1972	1973	1974	1975	1976	1977	1978, proposed
Positions	24	30	30	30	30	30	30
Extramural (thousands)	$75	$13	$28	$235	$40	$86	$60
Total funds (thousands)	$598	$590	$638	$1,000	$770	$770	$830

B. Collection and/or analysis of health data

The program resources were used to fund a contract with the Southern Research Institute to provide a thorough examination of the possible correlation of an increased incidence of congenital anomalies in children born on a U.S. Army base with a high concentration of operational radars.

	Fiscal year—						
	1972	1973	1974	1975	1976	1977	1978, proposed
Positions							
Extramural (thousands)		$13	$28	$9			
Total funds (thousands)		$13	$28	$9			

C. Collection and/or analysis of environmental data

This program includes measurement of non-ionizing radiation levels in the general environment and calculation, measurement, and evaluation of specific types of sources. The calibration and field testing of a mobile radiofrequency measurements systems were completed in 1975. Data on ambient environmental levels in urban areas were collected; evaluations were also made of several problems related to specific sources or source types. The data are now being studied and population exposure is being computed on the basis of a population locator code.

	Fiscal year—					
	1973	1974	1975	1976	1977	1978, proposed
Positions	4	4	6	6	6	6
Extramural (thousands)				$10		
Total funds (thousands)	$96	$207	$197	$207	$200	$200

II. IONIZING RADIATION

A. Studies to determine human health effects

The program resources were primarily used to support intramural research on the age-sensitivity to bone tumor induction resulting from prolonged ingestion of radiostrontium by cats. Lower level efforts were directed towards the teratogenic, reproductive, behavioral, and premature aging and tumorigenic efforts of continuous exposure to tritium on the rat and tissue distribution, kinetics, hematologic, and late effects of exposure to guinea pigs and rats to krypton-85 gas.

	Fiscal year—						
	1972	1973	1974	1975	1976	1977	1978, proposed
Positions	25	25	9	4	2		
Extramural (thousands)	$195	$195		$200		$28	
Total funds (thousands)	$799	$856	$275	$350	$70	$28	

B. Criteria and standards development

The purpose of this program is to protect, cost-effectively, the health and welfare of man and the environment from adverse effects due to radiation exposure and in balance with the benefits of the particular radiation producing activity. There are potential sources of radiation exposure where existing controls are deficient or non-existent and where there is a need to promulgate generally applicable radiation protection standards to provide this protection. Federal Radiation Guidance is being developed for certain areas where there is a demonstrated need to use the Federal Radiation Council transferred authority. Such guidance to other Federal agencies provides the technical basis for reducing unnecessary radiation exposure and keeping the exposure of the general public "as low as reasonably achievable." Other activities for protecting cost-effectively the health and safety of the public are carried out under the authorities set forth under the Safe Drinking Water Act of 1974, the Ocean Dumping Act of 1972, as amended, and the Federal Water Pollution Control Act of 1972, as amended.

Activities included in this project are:

1. Standards for the normal operation of the uranium fuel cycle promulgated in fiscal year 1977 for planned releases from nuclear facilities;
2. Amendments to the UFC standard for control of carbon-14 planned for FY 1978.
3. Guidance for cleanup and restoration of areas already contaminated with plutonium (fiscal year 1977) and standards for release of plutonium.
4. Guides to limit control of radiation exposure from naturally-occurring radioactive materials. Guides for acceptable levels of radiation in structures built on phosphates lands will be published in fiscal year 1977. Draft guidance will be developed in fiscal year 1978 for mineral and extraction industries and land use.
5. Environmental standards for all classes of radioactive wastes. Standards for disposal of high-level wastes are expected to be completed in fiscal year 1978; standards for low-level wastes and for ocean disposal will be completed in fiscal year 1983 and 1985 respectively.
6. Protective Action Guides are developed for use in emergency response planning for unplanned nuclear releases from fixed facilities.
7. Interim Primary Drinking Water Regulations were published in fiscal year 1976 under the EPA program to develop drinking water regulations to protect public health to the extent cost-effectively feasible.
8. Draft Guidance to reduce does from medical diagnostic radiology without jeopardizing diagnostic effectiveness was developed in fiscal year 1977.
9. Guidance for occupational exposure limits for radiation workers will be published in fiscal year 1977.

	Fiscal year—					
	1973	1974	1975	1976	1977	1978
Positions	39	39	48	50	[1] 59	51
Extramural (thousands)	$350	$115		$125	$2, 177	
Total funds (thousands)	$1, 282	$966	$1, 149	$1, 251	[2] $3, 718	1, 229

[1] Includes 8 overtarget positions.

[2] Includes $2,475,000 overtarget.

C. State/Federal liaison

This project includes staffing of EPA Regional Offices with representatives of the Office of Radiation Programs, the provision of direct assistance to State and local governments, and assistance to other Federal agencies in areas where EPA possesses special capabilities. A program of academic training grants was terminated in 1974. The Regional Office serves as the local point for assistance to States with unique radiation problems, providing technical and program consultation and assistance to States where required; responding to public and Congressional inquiries; stimulating productive functioning of the Regional Training Committees to meet State training needs; and facilitating and coordinating ORP activities with States. Commencing in fiscal year 1976, Regional Offices undertook the review of Environmental Impact Statements for light-water-cooled nuclear power reactors. Headquarters and Regional Offices are involved in the development of emergency response capabilities, including the development, testing, evaluation, modification and maintenance of State emergency response plans, and the publication of a manual for use of Protective Action Guides. States are also supported through the provision of radiochemical analyses of special environmental samples at EPA's two radiation field facilities as requested. EPA's specialized monitoring capabilities are made available to other Federal agences on a cost-reimburseable basis for such activities as launches of SNAP devices for Cape Kennedy.

	Fiscal year—					
	1973	1974	1975	1976	1977	1978
Positions	40	40	42	25	25	25
Extramural (thousands)	[1] $483	[1] $83				
Total funds (thousands)	$1,439	$1,013	$1,000	$613	$650	$728

[1] Academic training grants.

Environmental Radiation Ambient Monitoring System (ERAMS)

D. Monitoring and surveillance

ERAMS is a program for continuing surveillance of radioactivity levels throughout the continental United States, Alaska, Hawaii, and U.S. territories. Through this system, over 7,000 individual analyses are performed annually on samples of air, airborne particulates, deposition, surface and drinking water, milk, and human bones. These samples are collected by State and local health agencies and analyzed at ORP's Eastern Environmental Radiation Facility (EERF) at Montgomery, Alabama. The present ERAMS emphasis is toward identifying trends in the accumulation of long-lived radionuclides in the environment. Therefore, specific analyses are made for uranium-234, uranium-238, plutonium-238, plutonium-239, carbon-14, tritium, strontium-90 and krypton-85. Measurements are also made for gross alpha and beta activity, and the gamma emitters, iodine-131, cesium-137, barium-140, and potassium-40.

Data from ERAMS were previously published in Radiation Data and Reports, however, the Office of Radiation Programs terminated this publication with the December 1974 issue. Since then a quarterly summary of raw data from the National Environmental Radiation Ambient Monitoring System network (which includes a limited amount of surveillance data from States) is reported in Environmental Radiation Data. These compendiums consist mainly of data tabulations without interpretation or discussion. These tabulations will be summarized annually and reported in ORP's report of the Radiological Quality of the Environment. An indepth analysis of ERAMS is being carried out to determine annual averages, to identify trends, to characterize the statistical distributions of data sets, to estimate individual and population doses, and to evaluate error terms for each of these determinations.

E. Medical, diagnostic and therapeutic

EPA's approach in this program is to work cooperatively with other Federal agencies concerned with x-ray exposures to the population. An Interagency Committee, chaired by EPA, has been established to develop guidance applicable to Federal health care programs on optimal procedures to assure that the radiation dose, from exposures, is as low as reasonably achievable while maintaining desirable image-quality and concomitantly to assure the efficacy of such procedures. The FDA/BRH is responsible for programs to reduce unnecessary patient exposure by setting performance standards for medical x-ray equipment.

Detailed guidance for Federal health care programs has been prepared for publication in the Federal Register in fiscal year 1977.

(Resources below are included in the figures cited for Criteria and Standards development.)

	Fiscal year—					
	1973	1974	1975	1976	1977	1978, proposed

Extramural (thousands)						
Total funds (thousands)	$48	$50	$53	$56	$60	$64

F. Collection and/or analysis of health data

The bulk of these resources were used to provide EPA's contribution to the support of the Atomic Bomb Casualty Commission in Hiroshima, Japan. The function of the ABCC is to gather and analyze data on the health status of survivors of the radiation exposures which occurred to the populations of Hiroshima and Nagasaki. Funds were also provided for an epidemiologic study of the incidence of thyroid tumors in several thousand young adults who had received radioiodine in diagnostic procedures and to support a study on the human cytogenetic effects of exposure to radon gas and its daughter products in homes built on uranium tailings.

Total funds (thousands)	$442	$305	$176	$389	$55		

G. Collection and analysis of environmental data

EPA conducts a National dose assessment program to determine the status of environmental radiation data, to analyze these data in terms of individual and population doses, and to provide guidance for improving radiation data. This program also provides information to guide the director of the Office of Radiation Programs by the analysis of radiation trends, identification of radiation problems, and support for establishing radiation protection guidance. This program makes maximum use of available data reported by others; additional data are acquired from EPA's Environmental Radiation Ambient Monitoring System, (reported as a separate project for purposes of this paper) and source related field studies.

Recent efforts include a study to determine ambient radiological air quality in the Ambrosia Lake area of New Mexico; a study to determine the impact of uranium mining and milling industry on ground water quality in the Grants Mineral Belt area of New Mexico; studies to determine remedial actions required at inactive uranium mill sites in the Western United States; and studies to determine radon levels on houses built on land reclaimed from phosphate mining in Florida, as well as sampling fruits and vegetables grown on reclaimed land for possible contamination.

An annual publication, Radiological Quality of the Environment, summarizes individual and population dose data for both ionizing and non-ionizing radiation, providing a comprehensive evaluation of radioactivity in the environment and indicates trends and problems.

	Fiscal year—					
	1973	1974	1975	1976	1977	1978, proposed

Total funds (thousands)	$1,147	$1,276	$823	$888	$965	$1,368

H. Technology assessment

The purpose of the program is to assess nuclear energy applications and documentation for EPA's radiation protection standards and to prepare technical guidance. The programs of other Federal agencies are influenced to assure protection of the environment and public health by review of their environmental impact statements, regulations, and proposed legislation as required by the National Environment Policy Act, Section 309 of the Clean Air Act of 1970, and Section 511 of the Federal Water Pollution Control Act of 1972, as amended. Advanced reactor systems and new applications of nuclear energy are evaluated on a case-by-case basis to learn in the development stage about potential environmental radiation problems. From such assessments EPA's position on the environmental and economic impact will evolve.

Comprehensive technical reviews of environmental impact statements are made for facilities and programs which have a potential radiological impact, so that any environmental problems can be identified in time to modify the facility or program. Engineering studies are pursued on selected aspects of power production, either through nuclear facilities or non-nuclear sources which have the potential for radiation exposure of the environment or the population. Recent issues studied include accident possibilities and siting of nuclear power plants; advanced nuclear technologies such as the liquid metal fast breeder reactor: alternatives for the management of various classes of radioactive wastes; and transportation of nuclear materials.

[1] Includes 7 regional office positions.

Question 1. What changes in jurisdiction between 1968 and 1977 affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Answer 1. EPA's primary radiation protection responsibilities were vested in the authorities transferred to the Agency by Reorganization Plan Number 3 of 1970. This plan created EPA. The major functions transferred at that time were to:

(a) Establish generally applicable environmental standards for the protection of the general environment from radioactive material (Atomic Energy Act of 1954, as amended).

(b) Advise the President with respect to radiation matters, directly or indirectly affecting health, including guidance for all Federal agencies in the formulation of radiation standards and in the establishment and execution of programs of cooperation with States (Atomic Energy Act of 1954, as amended). This authority had been previously vested in the President's Federal Radiation Council.

(c) Collect and provide information to the public on environmental levels of radiation (Public Health Act, as amended).

(d) Provide States Assistance (Public Health Service Act, as amended).

In addition to the Reorganization Plan, the Agency is authorized by the National Environmental Protection Act of 1969 to review the environmental impact statements of major Federal actions significantly affecting the quality of the human environment.

Subsequently EPA was authorized to: (a) issue permits for dumping radioactive materials into ocean waters (Marine Protection, Research and Sanctuaries Act), and (b) propose and promulgate primary and secondary drinking water regulations (Safe Drinking Water Act).

Attached to these responses is an appendix which contains an overview of Federal and State Radiation Control Functions and Authorities in major program areas. The information in the appendix will provide a broader concept of radiation protection activities within the Executive Department.

Since its formation, EPA's basic radiation protection authorities have not been affected by the emergence of new agencies. However, on many occasions the extent of the Agency's authority has been challenged by other agencies. For example, the Atomic Energy Commission (replaced by the Nuclear Regulatory Commission (NRC)) and the Energy Research and Development Administration (ERDA) challenged EPA's authority to set a generally applicable environmental standard for the specific facilities in the uranium fuel cycle. This issue was resolved satisfactorily by EPA and NRC and culminated in the issuance of EPA's uranium fuel cycle standards, which are implemented through regulations issued by NRC.

More recent examples of possible overlap of the Agency's authority are those by the Department of Health, Education, and Welfare (DHEW) related to Federal Gudiance in the fields of healing arts and nonionizing radiation and those by the Department of Labor (DOL) in formulating guides for occupational radiation exposure. Pursuant to EPA's Federal guidance responsibility, broad guidance in radiation protection is developed and recommended by the Administrator to the President for his approval. Approved guides then became the basis for regulations promulgated by Federal agencies in accordance with their specific responsibilities. It is in this context that efforts are made to resolve any differences with DHEW and DOL, and in fact, a memorandum of understanding has been signed with DHEW to provide for cooperative efforts in radiation protection for the healing arts. A copy of the memorandum of understanding is attached. (See 42 Fed. Reg. 5123–24, January 27, 1977.)

Question 2. Would you please describe the nature of the contacts between your organization and State groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with State agencies? Is there any confusion concerning respective responsibilities of State and Federal agencies?

Answer 2. The Agency's contact with State groups in the radiation field are achieved through various means. First the 10 Regional Office maintain direct contact with the States in their locality, and each has a staff member designated for radiation protection activities.

A second means is the Conference of Radiation Control Program Directors, Inc. (CRCPD). This organization is sponsored by EPA, NRC and the Food and Drug Administration (FDA) of DHEW. The membership of the Conference consists of State and local radiological control program directors. The objectives of the CRCPD are to:

(a) Promote radiological health in all aspects and phases.

(b) Coordinate radiological health activities of governmental agencies.

(c) Encourage the interchange of experience among radiation control program directors.

(d) Collect and make accessible to all radiation control program directors in official administrative positions such information and data as might be of assistance to them in the proper fulfillment of their duties.

The Federal agencies work closely with the Conference throughout the year to accomplish these objectives. The Agency has found the Conference to be an affective body for assuring coordination between Federal and State radiation control programs.

Attached is a copy of the Interagency Agreement EPA has with FDA to provide support of the CRCPD. FDA has a similar agreement with NRC. This attachment will provide a better understanding of this type of Federal and State coordination.

On several occasions EPA has been requested by a State to assist them in completing a project or performing a study. In these situations EPA coordinates its findings, plans and recommendations with the State authorities.

Two recent examples of State assistance are: The evaluation of the radiological impact of building houses on reclaimed phosphate land in Florida and the evaluation of the radiation problems associated with using mill tailings in building construction of Grand Junction, Colorado. These studies and resulting recommendations were continuously coordinated with State and local health officials.

The Safe Drinking Water Act, which includes radioactivity, allows States to accept responsibility for enforcement upon approval by EPA of the State's plan. EPA is required to assist the States to develop their capability to assume this responsibility. If a State cannot or does not accept this responsibility, then EPA is required to implement the Safe Drinking Water Act within that State.

The Office of Radiation Programs (ORP) of EPA operates a nationwide Environmental Radiation Ambient Monitoring System (ERAMS) to provide for the continuing surveillance of radioactive levels throughout the United States and its territories. Through this system, over 7000 individual analyses are performed annually in samples of air, airborne particulates, deposition, surface and drinking water, milk and human bones. These samples are collected by the State and local health agencies. ORP expands its ERAMS operation through the States after nuclear weapons atmospheric tests are conducted.

In another interagency program with the Federal Preparedness Agency, the Bureau of Radiological Health (BRH) of Food and Drug Administration, Energy Research and Development Administration, Department of Transportation, Defense Civil Preparedness Agency, Federal Disaster Assistance Administration and Nuclear Regulatory Commission, EPA advises and assists the States to develop emergency response plans for radiation incidents involving fixed nuclear facilities and transportation.

The above examples represent the various mechanisms employed by the Agency in maintaining contact with State and local officials. While these mechanisms tend to minimize confusion concerning the responsibilities of State and Federal agencies, there are occasions when confusion exists. An example of one such occasion is the responsibility for financing the cleanup of abandoned uranium mill tailings piles in the West. There existed no mechanism for the Federal government to implement a program of cleanup and restoration. Similarly, the States involved did not consider the problem their responsibility. Consequently, ERDA and EPA at the request of the Joint Committee on Atomic Energy were required to analyze the problem and determine a feasible solution. There remains some confusion between the States and the Federal government over which one will finance the cleanup and restoration of these lands.

Another example of confusion of authority is the question of Federal or State responsibility for solving the various problems associated with the high-level radioactive waste at West Valley, New York. These problems have not been resolved as of this date.

Question 3. Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved. Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Answer 3. Because radiation protection involves exposure arising from a variety of sources, it is extremely important that public health and environmental protection measures be derived from a basic source of guidance and not reflect as a basic premise other goals, such as energy production or radiation application in medicine. Within the Federal sector such a source exists in the Federal Radiation Council authority held by the EPA Administrator. Full recognition and utilization of this authority, complemented by appropriate regulation by Federal agencies having regulatory responsibilities, could assure the required public health and environmental protection. Thus, after Federal Radiation Guidance has been promulgated, other agencies of the Federal government charged with responsibilities for regulation of specific areas of radiation protection must implement appropriate control and enforcement programs.

At the present time there are some areas where regulatory and legislative gaps may exist. These include the control of radiation from (a) tailings from inactive uranium milling, phosphate and other extraction facilities, (b) various sources of enhanced exposure from naturally-occurring radioactive materials, and (c) ambient levels of non-ionizing radiation. Further analyses of these problems are required before the specific need for legislation can be determined.

Resources are never wholly adequate to meet problem assessment and regulation development needs for any EPA regulatory program. However, we feel that proper priority attention can generally be handled within present funding levels.

Question 4. What is your reaction to the proposals to consolidate all Federal radiation activities into one Federal radiation agency?

Answer 4. Consolidation of all Federal radiation protection programs into one Federal radiation agency has some merit. Through such an agency jurisdictional disputes and program duplication could conceivably be eliminated and there would exist one focal point in the Administration concerning radiation protection policies. In addition, such an agency could also conceivably more effectively compete for resources, eliminate multiple agency reporting requirements now imposed on State governments, and simplify Federal-State government relationships.

However, there are alternatives other than consolidation into one Federal agency. For example, EPA's Federal Radiation Council (FRC) authority could be strengthened through encouraging Federal agency cooperation. The FRC authority currently has the broad and comprehensive responsibility to serve as a focal point for national radiation protection policies and for developing recommendations for Federal guides. It could be expanded to include mandates for better review of national protection programs, monitoring and environmental and public health assessments. Other Federal agencies would retain their regulatory responsibilities and implement regulations within their legislative mandates to insure compliance with EPA's standards and guidelines.

EPA SUBMISSION

APPENDIX 1

FEDERAL AND STATE RADIATION CONTROL FUNCTIONS AND AUTHORITIES IN MAJOR PROGRAM AREAS

A. FUNCTION

Advise the President with respect to radiation matters, directly or indirectly affecting health, including guidance for all Federal agencies in the formulation of radiation standards and in the establishment and execution of programs of cooperation with States.

BASIC AUTHORITY

Atomic Energy Act of 1954, as amended.

AUTHORITY TRANSFERRED BY

Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

Environmental Protection Agency.

B. FUNCTION

Regulation of possession, use, and production of source material, byproduct material, and special nuclear material to provide for the common defense and security and to protect the health and safety of the public.

"Source material" means (1) uranium or thorium, or any combination thereof, in any physical or chemical form or (2) ores which contain by weight one-twentieth of one percent (0.05 percent) or more of (i) uranium, (ii) thorium or (iii) any combination thereof.

"By product material" means any radioactive material (except special nuclear material) yielded in or made radioactive by exposure to the radiation incident to the process of producing or utilizing special nuclear material.

"Special nuclear material" means (1) plutonium, uranium 233, uranium enriched in the isotope 233 or in the isotope 235, and any other material determined by the NRC to be special nuclear material; or (2) any material artificially enriched by any of the foregoing.

LIMITATIONS

This authority does not provide control of naturally-occurring radioactive material, such as radium, not specifically listed as "source material," or of uranium or thorium in concentrations less than that specified, or of radioactive material produced by an accelerator or other means not specified. In addition, certain uses of uranium and thorium are exempt from regulation (10CFR40).

BASIC AUTHORITY

Atomic Energy Act of 1954, as amended.

AUTHORITY TRANSFERRED BY

Energy Reorganization Act of 1974 (PL 93-438).

RESPONSIBLE AGENCY

Nuclear Regulatory Commission (through agreement with NRC, certain States have assumed specific regulatory authorities from NRC).

C. FUNCTION

Consider the environmental impact of high voltage transmission lines.

LIMITATIONS

Applicable only to such lines originating at nuclear generating plants.

BASIC AUTHORITY

Atomic Energy Act of 1954, as amended (licensing of plants). National Environmental Policy Act of 1969.

AUTHORITY TRANSFERRED BY

Energy Reorganization Act of 1974 (PL 93-438).

RESPONSIBLE AGENCY

Nuclear Regulatory Commission.

D. FUNCTION

Regulate the presence of radioactive materials in or the use of radiation with foods and drugs. Regulate the use of radiopharmaceuticals.

BASIC AUTHORITY

Food Additives Amendment of 1958 (PL 85-929). Federal Food, Drug and Cosmetics Act and Sec. 351 of Public Health Service Act.

RESPONSIBLE AGENCY

DHEW (FDA).

E. FUNCTION

Those functions vested by law in the Secretary of HEW or the DHEW which were administered through the Environmental Health Service and carried out by the Bureau of Radiological Health insofar as they pertain to regulation of radiation from consumer products, including electronic product radiation, and research, technical assistance, and training related to regulation of radiation from consumer products.

LIMITATIONS

Regulatory authority exists only for control of electric product radiation, not for radiation from all consumer products.

BASIC AUTHORITY

Public Health Service Act, as amended (section ——) including the Radiation Control for Health and Safety Act of 1968 (PL 90-602).

AUTHORITY TRANSFERRED BY

Authority specifically retained in DHEW by Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

DHEW (FDA-BRH).

F. FUNCTION

Those functions vested by law in the Secretary of HEW or the DHEW which were administered through the Environmental Health Service and carried out by the Bureau of Radiological Health insofar as they pertain to occupational exposures to radiation, and research, technical assistance, and training related to occupational exposures to radiation.

LIMITATIONS

No specific regulatory authority related to occupational radiation exposures; only general authorities and functions conferred by the Public Health Service Act would be included.

BASIC AUTHORITY

Public Health Service Act, as amended (section ——).

AUTHORITY TRANSFERRED BY

Authority specifically retained in DHEW by Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

DHEW (FDA-BRH).

G. FUNCTION

Those functions vested by law in the Secretary of HEW or the DHEW which were administered through the Environmental Health Services and carried out by the Bureau of Radiological Health insofar as they pertain to radiation as used in the healing arts, and research, technical assistance, and training related to radiation as used in the healing arts.

LIMITATIONS

No specific regulatory authority for radiation as used in the healing arts except for performance standards to control radiation emissions from electronic products used in the healing arts. General authorities and functions conferred by the Public Health Service Act would be included.

BASIC AUTHORITY

Public Health Service Act, as amended (section ----), including the Radiation Control for Health and Safety Act of 1968 (PL 90-602).

AUTHORITY TRANSFERRED BY

Authority specifically retained in DHEW by Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

DHEW (FDA-BRH).

H. FUNCTION

Establish generally applicable environmental standards for the protection of the general environment from radioactive material. As used herein, standards mean limits on radiation exposures or levels, or concentrations or quantities of radioactive material, in the general environment outside the boundaries of locations under the control of persons possessing or using radioactive material.

LIMITATIONS

This function derives from the AEC as administered through its Division of Radiation Protection Standards. Hence, it is applicable only to those radioactive materials and/or facilities subject to regulation by the AEC (now NRC). Clarification of this function related to the uranium fuel cycle was provided by the Director of the Office of Management and Budget who wrote on December 7, 1973: "EPA should discontinue its preparations for issuing, now or in the future, any standards for types of facilities; the EPA should continue under its current authority, to have responsibility for setting standards for the total amount of radiation in the general environment from all facilities combined in the uranium fuel cycle, i.e., an ambient standard which would have to reflect AEC's findings as to practicability of emissions controls."

BASIC AUTHORITY

Atomic Energy Act of 1954, as amended.

AUTHORITY TRANSFERRED BY

Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

Environmental Protection Agency.

I. FUNCTION

1. Research, investigations, training, information, technical assistance, water quality surveillance, grants and contracts.
2. Discharge of any pollutant into navigable waters by any person is unlawful except in compliance with various sections of the FWPCA.
3. Establish effluent limitations for point sources.
4. Discharge of any radiological warfare agent or high-level radioactive waste into navigable waters is unlawful, notwithstanding any other provisions of the Act.
5. Approve State water quality standards which are consistent with the requirements of the FWPCA, or propose and promulgate water quality standards for a State.
6. Develop and publish criteria for water quality.
7. Publish guidelines for effluent limitations.
8. Issue information on identifying and evaluating nonpoint sources of pollution, processes, procedures, and methods to control pollution.
9. Promulgate guidelines establishing test procedures for the analysis of pollutants, monitoring requirements, reporting requirements, enforcement provisions, and funding, personnel qualifications, and manpower requirements for State programs.
10. Publish a list of categories of sources and propose and promulgate regulations establishing Federal standards of performance for new sources within the categories.
11. Publish a list of toxic pollutants or combination of such pollutants; propose and promulgate effluents standards or prohibitions for such pollutants.
12. Right to inspect, monitor, and right of entry.
13. Policy of U.S. that there should be no discharges of hazardous substances into or upon the navigable waters of the U.S., adjoining shorelines, or into or upon the waters of the contiguous zone. Administrator shall develop and promulgate regulations designating as hazardous substances such elements and compounds which, when discharged in any quantity present an imminent and substantial danger to the public health or welfare, including fish, shellfish, wildlife, shoreline, and beaches. The President shall by regulation determine those quantities of any hazardous substannces the discharge of which, at such times, locations, circumstances, and conditions, will be harmful to the public health or welfare of the U.S., including fish, shellfish, wildlife, and public and private property, shorelines, and beaches. Discharge of hazardous substances in harmful quantities as determined by the President is prohibited, except where permitted in quantities and at times and locations or under such circumstances or conditions as the President may, by regulation, determine not to be harmful. (Authority of the President as shown above has been delegated to the Administrator of EPA by E.O. 11735.)
14. Issue permits for the discharge of any pollutant, or combination of pollutants, under certain conditions.

NOTE.—The term "pollutant" means dredged spoil, solid waste, incinerator residue, sewage, garbage, sewage sludge, munitions, chemical wastes, biological materials, radioactive materials, heat . . . discharged into water.

"Toxic pollutant" means those pollutants, or combinations of pollutants, including disease-causing agents, which after discharge and upon exposure, ingestion, inhalation or assimilation into any organism, either directly from the environment or indirectly through food chains, will, as the basis of information available to the Administrator, cause death, disease, behavioral abnormalities, cancer, genetic mutations, physiological malfunctions (including malfunctions in reproduction) or physical deformations, in such organisms or their offspring.

The term "pollution" means the man-made or man-induced alteration of the chemical, physical, biological, and radiological integrity of water.

LIMITATIONS

The following "comment" is included as part of 40 CFR 1, Section 125.1(x):

The legislative history of the Act reflects that the term "radioactive materials" as included within the definition of "pollutant" in section 502 of the Act covers only radioactive materials which are not encompassed in the definition of source, byproduct, or special nuclear materials as defined by the Atomic Energy Act of 1954, as amended, and regulated pursuant to the latter Act. Examples of radioactive materials not covered by the Atomic Energy Act and, therefore, included within the term "pollutant" are radium and accelerator produced isotopes.

This interpretation of the limitations of the EPA authority was challenged by the Colorado Public Interest Research Group, upheld by the lower Court, appealed to and overruled by the U.S. Court of Appeals for the Tenth Circuit, and now will be reviewed by the Supreme Court.

BASIC AUTHORITY

Federal Water Pollution Control Act, as amended.

AUTHORITY TRANSFERRED BY

Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

Environmental Protection Agency.

J. FUNCTION

1. Research, demonstrations, training, information, grants and contracts.
2. Publish guidelines for solid waste recovery, collection, separation, and disposal systems, which shall be consistent with public health and welfare, and air and water quality standards and adaptable to appropriate land-use plans.
3. Recommend model codes, ordinances, and statutes which are designed to implement purposes of this chapter.
4. Each Executive agency which issues any license or permit for disposal of solid waste shall, prior to the issuance of such license or permit, consult with the Secretary to insure compliance with guidelines recommended and the purposes of this chapter.
5. Submit a comprehensive report and plan for the creation of a system of national disposal sites for the storage and disposal of hazardous wastes, including radioactive, toxic chemical, biological, and other wastes which may endanger public health or welfare.

BASIC AUTHORITY

The Solid Waste Disposal Act, as amended.

AUTHORITY TRANSFERRED BY

Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

Environmental Protection Agency.

K. FUNCTION

1. Propose and promulgate national primary and secondary drinking water regulations; provides for State primary enforcement responsibilities.
2. Propose and promulgate regulations for State underground injection control program; provides for State primary enforcement responsibilities.
3. Upon receipt of information that a contaminant which is present in or is likely to enter a public water system may present an imminent and substantial endangerment to the health of persons, and that appropriate State and local authorities have not acted to protect the health of such persons, may take such actions as he may deem necessary in order to protect the health of such persons, including issuing such orders as may be necessary to protect the health of persons who are or may be users of such system, and commencing a civil action for appropriate relief, including a restraining order or injunction.
4. Research, technical assistance, information, training of personnel, and grants.

LIMITATIONS

Public water system is defined as having at least 15 service connections or regularly serves at least 25 individuals.

BASIC AUTHORITY

Safe Drinking Water Act (PL 93–523) amends the Public Health Service Act by adding a new Title XIV—Safety of Public Water Systems.

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

Environmental Protection Agency.

L. FUNCTION

1. Publish a list of air pollutants which have an adverse effect on public health and welfare; issue air quality criteria for each listed pollutant; propose and promulgate national primary and secondary air quality standards for each pollutant.
2. Publish a list of categories of stationary sources which may contribute significantly to air pollution which causes or contributes to the endangerment of public health or welfare; propose and promulgate Federal standards of performance for new sources within a category.
3. Publish a list of hazardous air pollutants (air pollutants to which no ambient air quality standard is applicable and which in the judgment of the Administrator may cause, or contribute to, an increase in mortality or an increase in serious irreversible, or incapacitating reversible, illness); propose and prescribe emission standards for such pollutants.
4. Upon receipt of evidence that a pollution source or combination of sources is presenting an imminent and substantial endangerment to the health of persons, and that appropriate State or local authorities have not acted to abate such sources, may bring suit to immediately restrain any person causing or contributing to the alleged pollution to stop the emission of air pollutants causing or contributing to such pollution or to take such other action as may be necessary.
5. Review and comment in writing on the environmental impact of any matter relating to duties and responsibilities granted pursuant to the Clean Air Act or other provisions of the authority of the Administrator, contained in any (a) legislation proposed by any Federal department or agency, (b) newly authorized Federal projects for construction and any major Federal agency action other than a project for construction to which section 102(2)(c) of PL 91–190 applies, and (c) proposed regulations published by any department or agency of the Federal Government. Such written comment shall be made public at the conclusion of any such review. In the event the Administrator determines that any such legislation, action, or regulation is unsatisfactory from the standpoint of public health or welfare or environmental quality, he shall publish his determination and the matter shall be referred to the Council on Environmental Quality.

LIMITATIONS

Certain exemptions may be granted by the President in the interest of National security. The Clean Air Act shall not be construed as superseding or limiting the authorities and responsibilities, under any other provision of law, of the Administrator or any other Federal officer, department, or agency.

BASIC AUTHORITY

The Clean Air Act, as amended.

AUTHORITY TRANSFERRED BY

Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

Environmental Protection Agency.

M. FUNCTION

Those functions vested by law in the Secretary of HEW or the DHEW which were administered through the Environmental Health Service, including the functions exercised by the Bureau of Radiological Health.

LIMITATIONS

This authority does not include those functions carried out by the Bureau of Radiological Health insofar as they pertain to (A) regulation of rediation from consumer products, including electronic product radiation, (B) radiation as used in the healing arts, (C) occupational exposures to radiation, and (D) research, technical assistance, and training related to (A), (B), and (C). No regulatory authority is included.

BASIC AUTHORITY

Public Health Service Act, as amended.

Pertinent general authorities and functions conferred by the Public Health Service Act include the following:

A. Research and Investigations

1. Conduct and promote coordination of research, investigations, experiments, demonstrations, and studies relating to the causes, diagnosis, treatment, control, and prevention of physicial and mental diseases and impairments of man.
2. Encourage, cooperate with, and render assistance to other appropriate public authorities, scientific instiutions, and scientists in the conduct of the foregoing.
3. Collect and make available information on such research and other activities.
4. Make available technical advice and assistance on the application of statistical methods to experiments, studies, and surveys.
5. Award grants and contracts for research, investigations, and studies.
6. Adopt such additional means as necessary and appropriate to carry out purposes of this section.

B. National Health Surveys and Studies

1. Make, by sampling or other appropriate means, surveys and special studies of the population to determine the extent of illness and disability and related information such as (a) number, age, sex, and occupation or activities of persons afflicted with chronic or other diseases or injury; (b) economic and other impacts of such conditions; and (c) environmental and social health hazards.
2. Develop and test new or improved methods for obtaining current data on illness and disability and related information.
3. Undertake research, development, demonstration, and evaluation relating to design and implementation of a cooperative system for producing comparable and uniform health information and statistics at the Federal, State, and local levels.
4. Make available the results of surveys and studies.

5. Authorized and directed to cooperate and consult with other interested Federal Departments or agencies and with State health departments.

C. Federal-State Cooperation

1. Assist States and their political subdivisions in the prevention and suppression of communicable diseases.
2. Cooperate with and aid State and local authorities in the enforcement of their quarantine and other health regulations.
3. Advise the several States on matters relating to the preservation and improvement of the public health.
4. Encourage cooperative activities between States with respect to comprehensive and continuing planning as to current and future health needs and the establishment and maintenance of adequate public services.
5. Train personnel for State and local health work.
6. May, at request of appropriate State or local authority, extend temporary assistance to States or localities in meeting health emergencies of such a nature as to warrant Federal assistance, and may require reimbursement for such aid.

D. Publication of Health Educational Information

Issue information related to public health for the use of the public.

AUTHORITY TRANSFERRED BY

Reorganization Plan No. 3 of 1970.

RESPONSIBLE AGENCY

Environmental Protection Agency.

N. FUNCTION

With respect to prevention, control, and abatement of environmental pollution at Federal facilities—

A. Provide technical assistance and advice.
B. Maintain review of Federal facilities' compliance with specified standards.
C. Provide liaison to assure that Federal actions are coordinated with State, interstate, and local programs.
D. Mediate conflicts between Federal agencies and State, interstate, or local agencies.
E. Develop in consultation with heads of other Federal agencies a coordinated strategy for Federal facility compliance with applicable specified standards, and issue such regulations and guidelines as are deemed necessary.
F. Maintain review of implementation of this order and report to the President on the progress of Federal agencies in implementing this order.

The radiation standards specified in this order include Federal guidance on radiation and generally applicable environmental radiation standards promulgated or recommended by the Administrator and adopted in accordance with the Atomic Energy Act, as amended (42 U.S.C. 2011), and rules, regulations, requirements, and guidelines on discharges of radioactivity as prescribed by the Atomic Energy Commission.

LIMITATIONS

Applicable only to Federal facilities.

BASIC AUTHORITY

Executive Order 11752.

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

Environmental Protection Agency.

O. FUNCTION

Dumping of radiological warfare agents or high-level radioactive waste into ocean waters is prohibited. Administrator may issue permits for dumping into ocean waters of other materials, including radioactive materials, when determined that such dumping will not unreasonably degrade or endanger human health, welfare, or amenities, or the marine environment, ecological systems, or economic potentialities.

BASIC AUTHORITY

Marine Protection, Research and Sanctuaries Act.

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

Environmental Protection Agency.

P. FUNCTION

1. Conduct research, studies, and investigations on the safety of consumer products; test consumer products.
2. Promulgate consumer product safety standards, including requirements as to performance, composition, contents, etc., or requirements that a consumer product be marked with or accompanied by clear and adequate warnings or instructions.
3. Under certain conditions may declare a consumer product a banned hazardous product.
4. May file action in court for seizure of an imminently hazardous consumer product.
5. May require manufacturer of any new consumer product to furnish notice and a description of such product to the Commission before its distribution in commerce.
6. May require product certification and labeling.
7. Carry out functions of the Federal Hazardous Substances Act.

LIMITATIONS

The Commission has no authority to regulate any risk of injury associated with a consumer product if such risk could be eliminated or sufficiently reduced by actions taken pursuant to the Occupational Safety and Health Act of 1970, the Atomic Energy Act of 1954, the Clean Air Act, or the Radiation Control for Health and Safety Act.

BASIC AUTHORITY

Consumer Product Safety Act (PL 92-573). Federal Hazardous Substances Act.

AUTHORITY TRANSFERRED BY

Consumer Product Safety Act transferred miscellaneous existing authorities to the Commission.

RESPONSIBLE AGENCY

Consumer Product Safety Commission.

Q. FUNCTION

Establishment of an occupational safety and health program, including promulgation of standards, enforcement, conduct of research, training, and cooperative programs with States.

LIMITATIONS

Does not apply to working conditions of employees with respect to which other Federal agencies, and State agencies acting under section 274 of the Atomic Energy Act of 1954, as amended, exercise statutory atuhority to prescribe or enforce standards or regulations affecting occupational safety or health.

BASIC AUTHORITY

Occupational Safety and Health Act of 1970 (PL 91-596).

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

Department of Labor (OSHA).

R. FUNCTION

Set health and safety standards for miners, including regulation of exposure of uranium miners to radon and radon daughters in mines.

BASIC AUTHORITY

Federal Metal and Non-Metallic Mine Safety Act (PL 89-577).

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

Department of the Interior (Bureau of Mines).

S. FUNCTION

Regulate for the safe transportation in interstate and foreign commerce of all hazardous materials, including radioactive materials, by all modes of transport, highway, rail, or water, and by all means.

LIMITATIONS

Postal shipments are under the jurisdiction of the U.S. Postal Service and are therefore excluded from this authority.

BASIC AUTHORITY

Department of Transportation Act (PL 89-670).

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

Department of Transportation (FAA, Federal Highway Administration, Federal Railroad Administration, and U.S.C.G.).

T. FUNCTION

Regulate radiofrequency and microwave sources used in communications, primarily based on consideration of interference.

LIMITATIONS

No statutory authority to control radiation health hazards, but could take this into account in the licensing procedures.

BASIC AUTHORITY

FCC—Communications Act of 1934, as amended, and Communications Satellite Act of 1962. OTP—Reorganization Plan No. 1 of 1970, and Executive Order 11556.

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

1. Federal Communications Commission (Civilian source).
2. Office of Telecommunications Policy (Government source).

U. FUNCTION

Regulate high voltage transmission lines.

LIMITATIONS

Applicable only to such lines originating at hydroelectric and pumped storage generating plants.

BASIC AUTHORITY

Federal Power Act, as amended.

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

Federal Power Commission.

V. FUNCTION

Comment on the environmental impact statements of all Federal agency recommendations or reports on proposals for legislation and other major Federal actions significantly affecting the quality of the human environment.

LIMITATIONS

None.

BASIC AUTHORITY

National Environmental Policy Act of 1969.

AUTHORITY TRANSFERRED BY

N/A.

RESPONSIBLE AGENCY

Any Federal agency which has jurisdiction by law or special expertise with respect to any environmental impact involved.

W. FUNCTION

Responsible for the radiation health and safety and environmental protection at Energy Research and Development Administration (ERDA) owned and operated and ERDA contractor operated facilities; engaging in and supporting environmental, biomedical, physical, and safety research related to the development of energy sources and utilization technologies.

LIMITATIONS

Certain classes of ERDA facilities are subject to regulatory control by the Nuclear Regulatory Commission, as defined in Section 202 of the Energy Reorganization Act of 1974.

BASIC AUTHORITY

Atomic Energy Act of 1954, as amended. Energy Reorganization Act of 1974.

AUTHORITY TRANSFERRED BY

Energy Reorganization Act of 1974.

RESPONSIBLE AGENCY

Energy Research and Development Administration.

STATE RADIATION CONTROL AUTHORITIES

In addition to Federal radiation control authorities, most of the States possess authority to control certain aspects of radiation. Many of the Federal statutes either mandate that States promulgate and enforce regulations, or permit the Federal authority to be delegated, through agreements, to the States. Where there is no Federal regulatory authority to control certain aspects of radiation, most of the States have enabling statutes and regulatory programs for such cotnrol.

Federal statutes that either mandate establishment of State regulatory programs or permit delegation to States include the following: Safe Drinking Water Act. Occupational Safety and Health Act of 1970. Federal Water Pollution Control Act, as amended. Atomic Energy Act of 1954, as.amended. Clean Air Act as amended.

As of June 30, 1974, a total of 47 States and Puerto Rico have enacted specific laws providing for the regulation of ionizing radiation. In the other States and the District of Columbia, authority for some aspects of radiation protection is assumed under general public health laws. State programs generally encompass regulation of X-ray facilities and use, all radioactive materials not under the control of the Nuclear Regulatory Commission, and for those States who have agreed to do so, regulation of radioactive materials formerly under the control of the Nuclear Regulatory Commission.

Pursuant to Section 274 of the Atomic Energy Act of 1954, as amended, the Nuclear Regulatory Commission may enter into agreements with States providing for the discontinuance of the regulatory authority of the Commission with respect to one or more of the following materials within the State:

1. byproduct materials;
2. source materials; and
3. special nuclear materials in quantities not sufficient to form a critical mass.

During the duration of such agreement, the State has the authority to regulate the materials covered by the agreement for the protection of the public health and safety from radiation hazards. As of December 31, 1974, 25 States have entered into such an agreement and now conduct a regulatory radiation control program for these materials.

As of June 30, 1973, 16 States had enacted legislation providing for the regulation of nonionizing radiation and four States have specific legislation for the registration of laser devices. In addition, five States and Puerto Rico have specific laws which establish minimum standards for the education, training, and experience of certain user groups that apply ionizing radiation to human beings for diagnostic or therapeutic purposes.

In an effort to achieve compatibility and some degree of uniformity among State radiation control programs, a document entitled "Suggested State Regulations for Control of Radiation" was published by the Council of State Governments in 1962 with the assistance of the U.S. Atomic Energy Commission and the U.S. Public Health Service, and periodically revised and updated. The Office of Radiation Programs, EPA, now participates in the revision effort in cooperation with the Nuclear Regulatory Commission, the Food and Drug Administration, the Conference of Radiation Control Program Directors, and the Council of State Governments. Generally most State radiation control regulations have been developed to be compatible with applicable parts of the Suggested State Regulations, but of course vary in comprehensiveness and effectiveness.

INTERAGENCY AGREEMENT BETWEEN THE BUREAU OF RADIOLOGICAL HEALTH FDA AND THE OFFICE OF RADIATION PROGRAMS, EPA

I. PURPOSE

The Conference of Radiation Control Program Directors, Inc., ("CRCPD"), whose membership consists of State and local radiological health program directors, was established in 1968 and incorporated in 1975. This organization was initially sponsored by the Bureau of Radiological Health, DHEW, and is now sponsored jointly by three Federal agencies—the Bureau of Radiological Health (FDA), the Office of Radiation Programs (EPA), and the Nuclear Regulatory Commission (NRC). The purpose of this agreement is to provide the mechanism for EPA to share in the cost of the FDA contract supporting and obtaining the services of the Conference of Radiation Control Program Directors, Inc. This contract is mutually beneficial and jointly funded.

II. SCOPE OF WORK

The objectives of the CRCPD are to promote radiological health in all aspects and phases; to coordinate radiological health activities of governmental agencies; to encourage the interchange of experience among radiation control program directors; and to collect information and data as might be of assistance to them in the proper fulfillment of their duties. The services of the CRCPD are used to assist the Federal agencies in indentification of radiation control problems and in the development and implementation of solutions to these problems. The CRCPD provides an interface between the sponsoring Federal agencies and the State radiation control programs, promoting better Federal-State relations and understanding, and facilitating the interchange and utilization of expertise and knowledge on radiological health problems of national concern.

A detailed scope of work, mutually agreeable to the sponsoring Federal agencies and the CRCPD, will be prepared annually as the basis for the annual contract. The scope of work for the current contract to be partially supported by EPA funds through his LAG, is shown as the attachment to the agreement.

III. PROVISIONS

The sponsoring Federal agencies—BRH (FDA), ORP (EPA), and NRC—shall share the cost of the annual contract approximately equally, with FDA being the lead agency and contracting agency. EPA's share (one-third of the annual contract cost) will be transferred to FDA as an advance for disbursal under the provisions of the FDA–CRCPD contract and shall be used only for funding of this contract.

Through representation on the Project Advisory Group, the EPA Project Officer shall participate in the development of the annual scope of work and any modifications thereto, in the review of work accomplished under the contract, and shall be the principal EPA point of contact for matters relating to this IAG and the CRCPD. As a sponsoring agency, EPA shall receive copies of or have access to all reports, data, proceedings, and other information developed by the CRCPD under the contract.

IV. DURATION OF AGREEMENT

This agreement shall become effective upon the latest date of execution as indicated below, and shall remain in effect indefinitely until terminated by either party upon 90-days written notice to the other party. It will be funded annually by amendment.

V. PROJECT OFFICERS

FDA: 1. John J. Boesen, Director, Program Planning and Evaluation Staff, Office of Associate Director for Administration, Bureau of Radiological Health, 5600 Fishers Lane, Rockville, Md. 20852, (301) 443–2797.

2. James W. Miller, D.D.S., Director, Radiation Operations Staff, HFO–106, Division of Field Operations, Executive Director of Regional Operations. 5600 Fishers Lane, Rockville, Md. 20852, (301) 443–4006.

EPA: R. J. Augustine, Ph. D., Regional Liaison, Office of Radiation Programs (AW–458), U.S. Environmental Protection Agency, 401 M. Street, S.W., Washington, D.C. 20460, (202) 755–4894.

VI. FUNDS:

Funds in the amount of approximately one-third of the estimated annual contract cost will be transferred as an advance from EPA to FDA and are to be disbursed only in support of the FDA–CRCPD contract. The total annual contract cost on a calendar year basis will depend on the detailed work scope developed for each year. For CY 1976, the estimated total cost is $100,000. EPA's annual share will be $33,300 of which approximately $25,000 will be transferred to FDA in FY 1976 and the balance, if needed, will be transferred in FY 1977 along with additional funds as required to support the CY 1977 contract. It is anticipated that normally EPA's share of the estimated contract cost will be transferred to FDA early in each fiscal year so that the funds will be available in FDA prior to the beginning of the calendar year to be covered by the FDA contract.

VII. AUTHORITY

The authority under which this agreement is entered into is provided for in the Public Health Service Act, 42 USC 201 et seq.

VIII. AGREED

ENVIRONMENTAL PROTECTION AGENCY,
W. D. ROWE, Ph. D.,
Deputy Assistant Administrator for Radiation Programs.
FOOD AND DRUG ADMINISTRATION,
LLOYD L. SUNDQUIST,
Director, Division of Contracts—Title and Grants Management.

WORK SCOPE CALENDAR YEAR 1976

Chief, Negotiated Contracts Branch.
Division of Contracts and Grants Management.
Thru: Director, Bureau of Radiological Health, Associate Commissioner for Science, Director, Division of Financial Management, Associate Director for Administration, HFX-10, Bureau of Radiological Health.

MEMORANDUM OF NEED: COORDINATE FEDERAL/STATE RADIATION CONTROL ACTIVITIES AND ASSIST IN SOLVING RADIATION CONTROL PROBLEMS

I. STATEMENT OF WORK

The Conference and Radiation Control Program Directors, composed of State and local radiological health program directors, was established in 1968 and incorporated in 1975. This Conference, which initially was sponsored by the Bureau of Radiological Health, is now sponsored jointly by the Food and Drug Administration, Bureau of Radiological Health, the Office of Radiation Programs of the Environmental Protection Agency, and the Nuclear Regulatory Commission.

The purpose of the Conference is to promote radiological health in all aspects and phases; to coordinate radiological health activities of governmental agencies; to encourage the interchange of experience among radiation control program directors; and to collect and make accessible to all radiation control program directors in official administrative positions such information and data as might be of assistance to them in the proper fulfillment of their duties.

The Conference shall:

A. Plan and hold an annual technical meeting of the Conference members and sponsors consisting of a general session, workshops and clinics for the following purposes:

General Sessions.—To present reports on the status of studies conducted during previous years, technical reports on new developments and task force reports of problems defined and assigned as recommended by the workshop reports, Conference, or sponsors.

Workshops.—To study and define identified problems and/or areas of mutual concern in radiation control and recommend action needed to resolve these problems. The workshop reports are submitted to the Conference for cost benefit evaluation and further action. Problems that require extensive study are assigned to a task force comprised of experts in that field for solving.

Clinics.—To demonstrate mutually beneficial techniques, procedures, and systems which have been developed by the sponsoring agencies for Conference members in radiation control.

B. Perform all administrative management functions required for the conduct of the annual technical meeting including site visits and selections, program planning, and facility arrangements.

C. Appoint and arrange for standing task forces to study, evaluate, and develop recommended actions and/or solutions to current identified problems. Reports generated by these task forces will be evaluated by the Executive Committee of the Conference and reported to the participating agencies. All administrative management functions required to support these task forces will be performed by the Conference.

Task forces and their charges for 1975–76 will be:

1. A Task Force on Evaluation and Distribution of Radioactive Sources and Devices Not Manufactured Under the Atomic Energy Act

To develop by March 1976 the criteria needed to perform an adequate evaluation of devices, sealed sources, foils, dials, and matrices which contain naturally occurring or accelerator produced radioactive material and factors regarding their interstate distribution. By means of these criteria to provide a mechanism for State-Federal control of the manufacture and distribution of subject sources and products not covered under the Atomic Energy Act. To further develop uniform criteria for radiologic hazard acceptability and to study the risk-benefit rates of the use of radioactive materials in consumer products or devices.

2. Task Force on Program Criteria

To develop criteria that can be used in the evaluation of the adequacy of a State radiation control program. Such criteria will also consider machanisms whereby it is assured that State programs are compatible with Federal programs in the enforcement of standards and regulations in the achievement of radiation protection.

3. A Task Force on the Measure of Program Effectiveness as Related to Radioactive Materials

To consider methods for, and devise actual procedures for, the measurement effectiveness for radioactive materials control programs. Priority should be given to identifying methods and/or indices for measuring the magnitude of the problem and the impact of the program on the reduction of needless exposure of the public, patient, and occupational worker from medical sources.

4. A Task Force on Nationwide Evaluation of X-ray Trends (NEXT)

To identify optimum components of a survey.

To provide for uniform data control.

To provide a system for assigning program priorities.

To provide a system for measuring program effectiveness.

To categorize and determine the relative frequency of the sources of poor radiographic quality as these exist in practice today.

To develop exposure ranges which can be recommended for use by participating States in aiding facilities in the maintenance of consistent high quality diagnostic radiography with minimal exposure to the patient.

5. A Task Force on State Credentialling Program for Allied Health Operators

To develop guidelines for implementing uniform credentialling system for radiation operators. Such uniform guidelines will provide for national reciprocity.

To study and evaluate the recommendations of Workshop No. 9 (Seventh Annual Conference, Hyannis, Massachusetts) and, where applicable, recommend action or implementation of these recommendations. To coordinate action with the Bureau of Radiological Health, Division of Training and Medical Applications.

6. A Task Force on Suggested State Regulations for the Control of Radiation

To review and update existing Council of State Governments Suggested State Regulations for Control of Radiation.

To recommend to the Conference changes in the existing model regulations.

To develop new regulations deemed necessary because of new technical developments on Federal requirements.

To strive for compatibility with pertinent Federal regulations during the processes of updating, changing, or developing new regulations.

7. A Task Force on Natural Radioactivity Contamination Problems

To provide assistance to the Federal agencies or the field in scoping the problem of contamination by natural radioactivity.

To assist in developing appropriate guidance and criteria.

To assess the impact of contamination by radioactivity in the environment in the Conference member-States.

To serve as a focal point for input of Conference member-States to the program of the Federal agencies.

8. A Task Force on Waste Management

To recommend specific criteria that can be used in defining what properties a material must possess in order to be acceptable for burial in commercial waste disposal sites.

To evaluate the various methods for the solidification of radioactive waste. To present these recommendations in a report from the CRCPD to the sponsoring agencies by September 30, 1976.

To develop these methods and criteria in cooperation with various Federal and/or State agencies having jurisdiction for possible promulgation as Federal and/or State guidelines criteria and regulations.

To serve as a focal point for the Conference with Federal agencies developing standards, regulations, or guidelines in all areas of radio-active waste management.

9. A Task Force on Bonding and Perpetual Care of Nuclear Licensed Facilities

To evaluate the needs for, and find a mechanism for initiating bonding; to coordinate and, where necessary, recommend Federal legislation to achieve this.

To investigate the availability of other viable supplements to bonding.

D. Establish a National Training Coordination Committee to evaluate the training needs of all the States. Review these needs on a regional basis and assess the training requirements that must be approached from the national level to solve problems encountered. Work with the sponsoring or other Federal agencies, universities, manufacturers, or other resources to develop the training needed in radiation control.

E. Appoint ten Regional Training Committees consisting of one member from each State and perform all administrative management functions required for their support to provide a focus for assessing the training needs of individual States, develop an inventory of training resources in radiological health within each State and establish a positive mechanism for communicating these resources to all State and sponsoring Federal agencies.

F. On an annual basis and/or as requested by the sponsors provide information on State and local efforts in achieving and maintaining comprehensive programs to effectively reduce or control population exposure to ionizing and non-ionizing radiation. The reports will include resources expended and activities performed in all aspects of radiation control.

G. Attend Radiation Advisory Committee meetings of supporting agencies to provide State technical experience into the subjects under advisement.

H. Establish technical committees within the Conference to provide guidance and assistance to the sponsoring agencies in developing national programs in radiation control.

I. Submit quarterly and annual reports of work accomplished and cost accounting to the supporting agencies.

II. RELATIONSHIP OF REQUIREMENTS TO FDA AND BUREAU STATUTORY MISSIONS

Contracting with the Conference of Radiation Control Program Directors will further unify the Federal/State partnership in reducing unnecessary exposure of the public to ionizing and non-ionizing radiation by retaining the services of the 500 radiation control specialists in State and local agencies to assist in identification of, resolving and implementing solutions for, radiation control problems pursuant to Sections 301 and 311 of the Public Health Service Act, as amended, and Sections 356 and 357 of Public Law 90–602 and the commensurate authority of the other Federal participating agencies.

It will coordinate State radiation control activities with programs of the sponsors; assist the participating Federal agencies in maintaining a national data bank on radiation control activities and provide technical data and expertise vital to the formulation of regulations, standards, and model legislation.

III. CO-PROJECT OFFICERS

John J. Boesen, Director, Program Planning and Evaluation Staff, Office of Associate Director for Administration, Bureau of Radiological Health, 5600 Fishers Lane, Rockville, Md.

James W. Miller, D.D.S., Director, Radiation Operations Staff, HFO–106, Division of Field Operations, Executive Director of Regional Operations, Food and Drug Administration, 5600 Fishers Lane, Rockville, Md.

IV. PROJECT ADVISORY GROUP

The Federal agencies liaison officers listed below will serve on the project advisory group:

Environmental Protection Agency.—Dr. Robertson J. Augustine (Health Physicist), Regional Liaison (AW–558), Office of Radiation Programs, U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, D.C.

U.S. Nuclear Regulatory Commission.—Mr. Sheldon A. Schwartz (Engineer), Special Assistant for State Relations, Office of International and State Programs, U.S. Nuclear Regulatory Commission, Washington, D.C.

V. PROSPECTIVE CONTRACTOR

Conference of Radiation Control Program Directors, Inc., 4815 West Markham Street, Little Rock, Ark.

The Contractor's representative will be:

Mr. Frank E. Wilson, Secretary-Treasurer, CRCPD, Bureau of Environmental Health Services, Department of Health, 4815 West Markham Street, Little Rock, Ark.

VI. PROCUREMENT PLANNING

See scope of work.

VII. DURATION OF CONTRACT

January 1, 1976, to December 31, 1976.

VIII. LEVEL OF EFFORT AND FUNDING

The participating Federal agencies shall share the cost equally with FDA the leading agency. Both the Environmental Protection Agency and the Nuclear Regulatory Commission will, through interagency agreement, transfer their costs to FDA for disbursal.

Estimated total cost: $100,000 ($33,333 per Federal agency)

Cost breakout (travel, per diem):	
Nine task forces	$36, 800
National training coordinator	700
Emergency response planning liaison	1, 000
Regional training committee (RTC) meeetings, (10 regions)	8,000
Executive committee meetings	5, 000
Executive commitee attendance at RTC meetings	1 ,000
Annual meeting site visits for 1977, 1978	1, 000
pre-1976 site visit	750
Program planning, 1976 meeting	750
1976 annual meeting, Springfield, Ill	25, 000
Total	80, 000
Estimated 25 percent overhead	20, 000

IX. RELEASE OF INFORMATION BY CONTRACTOR

The release of information developed under this contract will be freely allowed.

ROBERT H. NEILL.

U.S. ENVIRONMENTAL PROTECTION AGENCY,
Washington, D.C., March 21, 1977.

JAMES W. MILLER, D.D.S.,
Dental Advisor, Office of Medical Affairs (HFX–4), Bureau of Radiological Health, Food and Drug Administration, Rockville, Md.

DEAR DR. MILLER: This letter, upon acceptance by FDA, will constitute an amendment to Interagency Agreement No. EPA–IAG–D6–H968 (FDA No. 224–76–6005). The purpose of this amendment is to (1) include the FY 1977 Work Scope, (2) specify the FY 1977 cost to EPA of $31,000, and (3) specify the accounting information for fiscal year 1977.

The indicated sections of the subject agreement are amended as follows:

II. SCOPE OF WORK

The detailed scope of work for the current contract, to be partially supported by EPA funds through this IAG, is enclosed with this letter amendment and becomes a part of the IAG.

IV. FUNDS

EPA's fiscal year 1977 share of the cost of the contract is estimated to be $31,000. Accounting information is as follows:

Appropriation No. 687/80108.
Account No. 767733A099.
Document Control No. A00069.
Object Class 25.70.

If this amendment is agreeable to you, please indicate FDA acceptance below and return one signed copy to the Office of Radiation Programs, Attn: Dr. R. J. Augustine (AW–458). A copy of the original IAG is enclosed for your information.

Sincerely yours,

EDWARD F. TUERK,
Acting Assistant Administrator for Air and Waste Management.

THE SURGEON GENERAL OF THE NAVY,
Washington, D.C.

Hon. ADLAI E. STEVENSON,
Hon. WENDELL H. FORD,
Committee on Commerce, Science, and Transportation,
U.S. Senate, Washington, D.C.

DEAR SENATORS STEVENSON AND FORD: I am very happy to provide the enclosed responses to your letter of 20 May 1977 concerning the Senate Committee on Commerce, Science, and Transportation hearings reviewing the current status of radiation research and regulatory programs.

The enclosed material is limited to the activities under the cognizance of the Bureau of Medicine and Surgery including the Navy's Extremely Low Frequency (ELF) program in support of Project SEAFARER.

The total biological/ecological program for Project SEAFARER is sponsored by the Naval Electronics Systems Command. It is supervised by a senior medical officer assigned to the SEAFARER Project Office on an additional duty basis and is thus available for inclusion. Several other Navy organizations and Systems Commands under the Chief of Naval Operations have various related radiation responsibilities particularly for environmental monitoring of field activities and ships. Should this information be required, it is recommended that the Secretary of the Navy or the Chief of Naval Operations be contacted.

The Bureau of Medicine and Surgery has three major responsibilities in the area of radiation. The first is to provide research into the biological effects and any attendant or potential hazard to the health of personnel. The second responsibility is to issue appropriate instructions on exposure standards and to provide for adequate personnel monitoring where needed. Pertinent Navy instructions are enclosed. Finally, it is responsible to be ready and capable for providing medical treatment of radiation injuries.

In the fifties and sixties, the Navy conducted a very active medical research effort in ionizing radiation at the Naval Radiological Defense Laboratory in San Francisco. With its closure in the late sixties, the medical research program in ionizing radiation was phased out.

In 1970, the radiation area was evaluated and decisions were made concerning future directions. It was decided that future medical research requirements for ionizing radiation could be met by the research program being conducted at the Armed Forces Radiobiology Research Institute in Bethesda, Maryland.

In the area of non-ionizing radiation, the Navy had long recognized the potential hazards of electromagnetic radiation (EMR) to other electronic devices, ordnance and fuel, but recognition and emphasis as to what effects EMR had upon personnel had been lacking. In reviewing the current state of the art, it was determined that there were many questions as to the acceptability of, and scientific basis for, the exposure standards. It was determined that the need for medical/biological information concerning the effects of EMR was of sufficient urgency and importance to warrant extraordinary attention and emphasis.

To address this problem, the Chief, Bureau of Medicine and Surgery, with concurrence of the Assistant Secretary of the Navy for Research and Development, issued BUMEDINST 6470.11 establishing an EMR Project Office. The instruction was recently updated as BUMEDINST 6470.11A. The Director of the Project Office provides a centralized point of contact within the Navy for coordination and integration of the Navy's medical research program in all areas of radiation, with particular emphasis on non-ionizing radiation. He also functions as the primary point of contact for liaison outside the Navy. In addition to the medical research program managed by the EMR Project Office, the Office of Naval Research (ONR) sponsors some research in this area. In FY 1977, ONR is sponsoring about $350K of biomedical research in addition to the Medical Department's program.

The two major areas of Navy research have been microwaves and extremely low frequency radiation, which supports Project SEAFARER. For your information, the total FY 1977 research program is summarized on the enclosed Office of Telecommunications Policy resume forms.

The entire Navy EMR program is closely coordinated with the other services through the Tri-Service EMR Panel and with other federal agencies via the "Interagency Side Effects Working Group" of the Office of Telecommunications Policy.

The Navy conducted only a small research program in laser medical hazards from 1970 through 1974. In 1974, the decision was made to discontinue research in this area since both the Army and Air Force had major programs and could carry out the required research in support of the Navy programs more effectively. Presently, research requirements are coordinated with the other services through the Tri-Service Laser Panel. The Naval Medical Research and Development Command has not sponsored any research in the area of ultrasound.

The following is in response to the specific questions asked in your letter (numbers conform with your question numbers).

1. There have been no major changes in the Medical Department's overall responsibilities in the radiation area. But as a result of new legislation and the creation of new agencies, there have been impacts on meeting these responsibilities.

The enactment of PL90-602 which established electronic product emission standards; the enactment of PL99-190, the National Environment Policy Act which requires Environment Impact Statements be prepared to assess proposed actions; the enactment of PL91-596, the Occupational Safety and Health Act which provides for establishment of occupational health standards; Executive Order 11807 of 20 September 1974 which directs federal agencies to be consistent with OSHA standards; the President's Reorganization Plan #3 establishing the Environmental Protection Agency (EPA) are examples of recent federal actions which have had an impact upon the radiation program. They have increased the Medical Department's need to provide liaison with a greater variety of federal agencies, to reissue some instructions to insure consistency with newly established standards, and to allocate some additional resources to insure compliance.

In the non-ionizing radiation research area, two major significant events were the establishment of the Electromagnetic Radiation Management Advisory Council (ERMAC) by the Office of Telecommunications Policy (OTP) and the assumption of a coordinating function for this area by OTP. These two events have resulted in, for the first time, a totally coordinated research program between the federal agencies involved.

Since almost every federal agency utilizes the electromagnetic spectrum in carrying out its basic mission, they each have certain responsibilites to insure that such use is compatible with the total environment. In addition, agencies with regulatory authority must insure that any rules or regulations issued have a clear balance between any risks and benefits.

Because of this multi-agency involvement, ERMAC and OTP have had a profound effect upon the current research program in EMR. The ERMAC program recommendations have provided concrete guidance to all agencies for research in this area. In addition, ERMAC has periodically reviewed each agency's program for scientific content and productivity. Its constructive comments on the Navy's research have been very helpful in improving the overall program.

The coordination effort provided by OTP through its "Side Effects Committee" has greatly increased the awareness of each federal agency to the activity and research of other federal agencies. To our knowledge, this area is the only one in the entire Federal Government where agencies with an active interest in a single area are aware of each other's programs and interact with each other on a day-to-day basis. As a result of this activity, a focal point for EMR research has been established within many agencies, relevant research has been identified and significant efforts have been made in developing cooperative interagency programs.

2. There is little interaction between the Navy Medical Department and state agencies. On occasion, Navy medical personnel have provided briefs to state officials concerning specific Navy systems. There has also been some contact with state agencies concerning specific environment impact statements of Navy systems, e.g., Project SEAFARER. There has not been any confusion concerning responbilities between the various states and the Navy Medical Department.

3. The present federal radiation regulatory programs could be significantly improved if the jurisdiction of each federal agency having regulatory authority was clearly defined. Priority attention should be given to insure that any regulations covering occupational, environmental, or product emissions have a consistent underlying rationale. These standards must also be based upon reliable and adequate research data. In the area of research program management the non-ionizing research program coordinated by OTP (as noted before) is excellent. Contrasted with this program there appears to be far less coordination of the other research areas by the involved federal agencies.

The Medical Department does issue appropriate health instructions based upon the guidelines and standards issued by the federal regulatory activities. In some cases where there are unique naval requirements, the Bureau develops its own regulations, but it is not considered to have wide regulatory responsibilities as the Occupational Safety and Health Administration or the Bureau of Radiological Health. At the present time there are adequate funds requested in outyear budgets for this function. However, there is a funding deficiency within our EMR research program. Based upon a detailed analysis by the EMR project Office, there is a critical need for an additional 1.5 million dollars in FY 1978 for new exposure equipment and facilities. This is a one-time requirement. In addition, there is a continuing requirement to increase the EMR Project Office program funding by 600 thousand dollars per year to more adequately meet the continuing research requirements.

4. The specific proposals for a single radiation agency referred to in your letter are not familiar to the Bureau. At first thought, such a proposal to consolidate all federal radiation activities into one federal agency sounds interesting. But with additional thought and reflection, it is difficult to comprehend. Radiation is a very broad term, so that what is included must be clearly defined. In a broad context of "all radiation activities", this would include all research, technology development, and regulatory activities for such diverse areas as nuclear reactors, radioactive drugs, medical diagnostic and therapeutic x-rays, management of electromagnetic spectrum, allocation of frequencies, and even regulation of 60 Hertz Power Systems.

In one small area of radiation, the Atomic Energy Commission (AEC) was such an all inclusive agency in being responsible for research, development, and regulation of ionizing radiation. The AEC was recently separated into two activities because of fears over possible conflicts of interests. Even then the AEC did not have jurisdiction over all ionizing radiation activities, i.e., the use of medical X-rays.

These are just a few of the many complex issues involved with the broad use the word "radiation". Without a clear and concise definition of what is meant by the term "radiation activity", it is certainly impossible to endorse such a concept.

It is the Medical Department's position that, because of the many facets to the term "radiation" and the use of one or more components of the broad radiation field by many federal agencies in the pursuit of their basic missions, a single federal radiation agency is not practical or desirable.

Sincerely,

W. P. ARENTZEN,
Vice Admiral, Medical Corps, U.S. Navy.

MATRIX SUMMARY

The only records maintained for the research programs are fiscal data. In-house personnel are assigned to work on individual work units by each laboratory commander as the needs arise. Thus personnel positions are not readily identifiable. Therefore, only funding data have been provided for each in-house research area vice number of positions. It should be noted that use of the funds includes civilian salaries, animal costs, and all supplies and equipment utilized for that research program. It does *not* include salaries for military personnel working in the research areas. In the non-research areas, best estimates for man-years and costs have been provided based upon records maintained in the Bureau of Medicine and Surgery.

Since the Navy programs are not alined exactly as described on the enclosed matrices, some arbitrary decisions have been made in the placement of Navy programs under the closest appropriate heading. A short description of the programs included under each heading follows.

1. *Studies to determine human health effects.*—All medical research utilizing animal studies whose goal is to determine or evaluate the biological effects of electromagnetic or ionizing radiation.

2. *Ecological efforts.*—Research which is directed toward evaluating the effects upon plant and animal life *per se* have been included in this area. Some studies involving animals are pure ecological, e.g., bird migration. While other studies apply equally to human health by extrapolating the results to man. In this case, the cost has been listed in the above category.

3. *Agricultural research.*—The Navy has not conducted any studies directed toward agriculture.

4. *Criteria and/or standards development.*—The Bureau of Medicine and surgery issues instructions related to health hazards and exposure standards. These instructions are consistent with federal standards issued by the regulatory agencies. Thus, the time devoted to their development is very minimal. Therefore, no man-years or funds have been listed.

5. *State/federal liaisons.*—The Navy Medical Department does not routinely maintain liaison with state governments in the radiation area. But on occasion medical personnel have interacted with state officials concerning specific Navy systems, e.g., a one-day briefing of state officials on the biomedical aspects of Project SEAFARER. Because of its infrequent nature, time and costs are negligible. In the environmental area the Navy is required to meet all federal, state, and/or local requirements. The interface with state and local authorities is the responsibility of the local Navy activity. It is the Department of Defense policy that all military installations close contact and cooperate fully with the local governments.

There is a continuing interaction and liaison between the Navy and other federal departments and agencies. Many are formal groups such as the "Side Effects Working Group", the "Tri-Service EMR Panel", and a formal Navy-Bureau of Radiological Health agreement for joint funding of some extra-mural research. In addition to interface at the senior managerial level, there is also a great deal of interaction by individual investigators at the laboratory level.

It is impossible to assign a dollar value to this liaison and just as difficult to estimate man-years since no one person devotes the majority of his time to this effort nor are any records kept for this type of activity. An unverifiable estimate of man-years has been made.

6. *Licensing, certification, inspection.*—The Navy does not routinely provide licensing or certification as this is performed by the responsible regulatory agency. Inspections are primarily performed by medical personnel in conducting the personnel monitoring programs. These have all been included in the next item, as man-years are impossible to separate.

7. *Monitoring and/or surveillance.*—Efforts directly related to monitoring personnel in an occupationally exposed environment, e.g., ionizing radiation survey program. The periodic physical examinations of occupational workers is performed by local medical facilities. No records are maintained at the Bureau, thus it is impossible to provide data on this aspect without a complete response from all the local medical facilities.

8. *Medical diagnostic, therapeutic.*—Most all medical facilities, ashore and afloat, have X-ray capabilities for diagnostic purposes. Several major hospitals also have full capabilities for therapeutic treatment with ionizing radiation. In addition, major hospitals provide nuclear medicine services. Many treatment facilities also have ultrasound diagnostic equipment and ultrasound and diathermy treatment capabilities. Personnel and fiscal records maintained by the Bureau of Medicine and Surgery are not structured to identify resources utilized by these line items. Personnel and funding data are impossible to estimate without a comprehensive survey of all Navy medical facilities. Needless to say, there is extensive use of ionizing and non-ionizing radiation within Navy medical facilities.

The Navy has not conducted medical research in the diagnostic and therapeutic uses of ionizing or non-ionizing radiation. Such research does not meet unique Navy needs. Therefore, it is considered to be the responsibility of the National Institutes of Health.

9. *Collection and/or analysis of health data.*—Specific health data or physical examinations collected and evaluated as part of a research program.

10. *Collection and/or analysis of environmental data.*—General environmental surveys of plants, animals, etc. to determine status of environmental conditions.

11. *Other biological or physical effects studies.*—Studies in this category include those investigating fundamental mechanisms or inferaction between EMR and biological systems, dosimetry studies, mathematical modeling, theoretical analysis of tissue absorption of EMR energy and instrument development.

12. *Other studies.*—Includes contract support for management studies, engineering support, literature search and acquisition, and costs of environmental impact statements.

EXTREMELY LOW FREQUENCY PROGRAM IN SUPPORT OF PROJECT SEAFARER

IH=Inhouse funds in thousands.
EM=Extra-mural funds in thousands.
T=Total funds in thousands.
MY=Man-years.

*Estimated man-years of contact with state governments concerning project SEAFARER.

**1976 includes funds for FY 1976 plus the transition quarter.

***In 1977. the contractor assumed responsibility for collecting health data on contract employees at SEAFARER's Wisconsin Test Facility as part of his normal corporate occupational program.

****The biological/ecological area is programmed for $1600K in FY 1978. but the exact program use of funds has not been determined pending the receipt of the National Academy of Sciences' report by the Navy.

DEPARTMENT OF THE AIR FORCE,
HEADQUARTERS UNITED STATES AIR FORCE,
Washington, D.C., June 8, 1977.

Hon. ADLAI E. STEVENSON,
Chairman, Science, Technology, and Space Subcommittee, U.S. Senate, Washington, D.C.

DEAR SENATOR STEVENSON: This is in response to your joint letter with Senator Wendall H. Ford of 20 May 1977 concerning federal radiation research and regulating programs.

The Air Force program information you requested is provided in the attached matrices and narrative descriptions. The answers to the specific questions in your letter touch upon broad policy matters which equally affect all Department of Defense agencies. The Director of Defense Research and Engineering, Department of Defense, has developed a coordinated response which fully represents our position on these questions.

Sincerely,

Lt. Gen. GEORGE E. SCHAFER, *U.S.A.F.*,
Surgeon General.

AIR FORCE RESEARCH AND REGULATORY PROGRAM DATA

1. Two sets of matrices are provided, one for ionizing radiation (Atch. 1) and one for non-ionizing radiofrequency radiation (RFR) (Atch 2). Data entries in each matrix block are coded in numerical order from one to three as follows:

1. Manyears expended, both military and civilian.
2. Extra-mural (contract) dollar costs in thousands.
3. Total dollar costs including extra-mural costs, and direct in-house costs and wages in thousands.

2. Narrative descriptions (Atch 3) are provided for each of the matrices headings and are keyed alphabetically as appendices (A thru L) to the headings starting from left to right, e.g., Appendix A provides a narrative description of information under Heading A, Studies to Determine Human Health Effects.

APPENDIX A—STUDIES TO DETERMINE HUMAN HEALTH EFFECTS

IONIZING RADIATION

Programs are Air Force specific and are designed to define aircrew performance decrements and exposure limits to ionizing radiation predicted to be received during air operations in a nuclear war. This research program on aircrew survivability/vulnerability, is coordinated within the Air Force at the Air Force Weapons Laboratory with the biomedical effects portion the responsibility of the USAF School of Aerospace Medicine (USAFSAM) under the Aerospace Medicine Division (AMD) at Brooks AFB, Texas, Tri-Service coordination has been achieved through the Defense Nuclear Agency (DNA) annual long range planning meetings and DNA Interagency funding of a portion of the Air Force crew vulnerability program. Specific descriptions of programs are given in attachment 1 to this Appendix.

NONIONIZING RADIATION

The early USAF program (1968-72) was primarily structured to evaluate the HF band (3–30 MHz) in support of the Over-the-Horizon Radars (441A and 414L). Surplus transmitters were acquired, fields were mapped, and calibrated by NBS, and primate data confirmed the adequacy of the 10mW/cm^2 safety level for these systems. The early R&D effort was primarily "reactive to developer and user needs; however, in the 1972–74 period, a long range R&D plan was formulated and coordinated with the US Army and Navy in the biomedical TCP. A comprehensive Tri-Service plan was developed in 1974–76 and submitted to ODDR&E. The USAF portion of this plan was largely oriented toward dosimetry, accurate determination of energy distribution and measurement, and appropriate scaling factors for extrapolation of animal data to man. The long range planning identified evolving phased array radar technology as an area requiring additional bioeffects data. The USAF has published a Required Operational Capability on this topic and initiated acquisition of a peak pulse power simulator to acquire essential effects data to support these new development efforts (PAVE PAWS, COBRA DANE, COBRA Judy, etc). The USAF program is closely coordinated with the other services and the OTP–ERMAC. Attachments 2 and 3 are copies of the FY 76 research summaries and project resumes provided to OTP.

ATTACHMENT 1 TO APPENDIX A—IONIZING RADIATION PROGRAM DESCRIPTION

Fiscal year 1968—Performance studies on rhesus monkeys were initiated using refined behavioral methods to produce data on reaction time changes as a function of ionizing radiation. The subjects were taught to perform tasks under highly motivating conditions so that high dose pulsed radiation effects could be assessed for nuclear weapon *"near miss"* threats.

Fiscal year 1969—High dose rate pulsed reactor studies were conducted to produce performance decrement curves for incapacitating and instantly debilitating aircrews in a simulated nuclear environment. Nausea, vomiting, blood pressure changes, etc., were measured.

Fiscal year 1970—Several animal species were studied to make extrapolations from among the primates (e.g., baboons, rhesus, cynomolgus, and squirrel monkeys) with respect to radiation response. The data provided confidence in certain extrapolation factors to human performance.

Fiscal year 1971—Primate Equilibrium Platform (PEP), displaying pitch and roll, were refined to allow collection of analog data for later development and application of linear mathematical models of aircrew performance.

Fiscal year 1972—Cognitive tasks vs simple work variables were studied as a function of ionizing radiation. The role of the decision-making processes and subsequent degradation of faculties is relevant to nuclear weapons delivery systems. These studies formed the basis of the math model on crew vulnerability as applied to the Space Shuttle and the B–52.

Fiscal year 1973—Studies were conducted at the AFRRI and Texas A&M reactors to establish a comparative data base for neutron/gamma ratios as effectiveness factors in disrupting aircrew performance. Vomiting studies were compared with emetic episodes among nuclear accident victims, and a nomogram developed as a guide to commanders.

Fiscal year 1974—Performance decrement curves for single pulses of ionizing radiation were refined using rhesus monkeys highly trained to perform precise psychomotor tasks which are similar but simplified versions of aircraft tasks. Tables of "sure safe", probable "mission completion", "probable kill", and "sure kill" were developed by dose (rad) and time (hours).

Fiscal year 1975—A refined estimation algorithm was perfected to quantify percent aircraft losses due to aircrew duty performance failures resulting from ionizing radiation and flashblindness. Such estimations represented "first look" quick responses to this very real HQ SAC interest item. This model led to later more sophisticated models of performance decrements.

Fiscal year 1976—Experiments to define the nausea and vomiting responses which can be expected to result from nuclear weapons irradiation have been conducted under a variety of likely exposure conditions. Statistical curves, ED_{50}—effective dose in fifty percent of the crews, have been produced to clarify this expected radiation threat to job performance.

Work was initiated to identify anti-nausea/vomiting drugs which aircrew members could use without adverse side effects (e.g., drowsiness, fatigue, etc). Crew hardening was the goal of this effort.

Work continued in mathematical models.

Fiscal year 1977—The current research program simulates tactical nuclear warfare in advanced bomber and fighter missions. Laboratory replications of ground based aircraft simulators located in radiation exposure facilities are used to evaluate high skill level performance decrements in rhesus monkeys. Missions of 1-hour; 10-hours; 12-hours and 72 hours have been performed with specific threat scenarios operating against AF weapons systems.

SUMMARY OF USAF RADIOFREQUENCY RADIATION BIOEFFECTS RESEARCH ACTIVITIES 1976—INPUT TO OTP/ERMAC

The USAF radiofrequency radiation (RFR) research program is comprised of contractual and in-house efforts in a ratio of about 65 percent and 35 percent respectively. It includes studies of: (1) RFR energy transfer, distribution and measurement, (2) effects on the central nervous system, (3) effect on immune systems, (4) cellular level effects, (5) medical device interference, (6) the effect of fractionated (long term) exposures, (7) effect of combined stress, and (8) the effects on behavior. More recent efforts are directed to the study of the specific biological consequences of man's exposure to a variety of pulsed RFR fields relative to continuous wave exposure.

As a part of the Tri-Service priority one effort (Energy Distribution and Measurement), the Air Force has undertaken a multi-year program to develop an RFR Dosimetry Handbook. The first edition of the handbook was prepared under Air Force contract by the University of Utah and published as USAF School of Aerospace Medicine Technical Report 76–35 in Sep 1976. More than 300 copies have been distributed to researchers in the United States and Europe. Initial response concerning the acceptance and use of this handbook is very favorable. Many of the calculated curves are being empirically validated. A follow-on program will seek out suggested improvements in the handbook's content and use. Furthermore, additional empirical data is being actively solicited for inclusion in the next edition (scheduled about Oct 77). In the final analysis, this effort should provide the necessary link between biological effects observed in irradiated animals and corresponding effects which might occur in man.

The Air Force approach to RF bioeffects studies is in direct support of Systems Development and relates observed response to thermally induced events and to specific absorbed power whether local, regional, or whole body. Energy transfer thresholds for such biological response and the relative efficiency of pulsed versus continuous wave exposures as well as the influence of duration of exposure, i.e., acute or chronic should lead to conceptual models from which any combination of threat modalities can be predicted. This approach could obviate the need for long and arduous research studies at every frequency level of interest and for each new mode of delivery.

The fact that RF radiation induced biological effects are frequency dependent suggests that safety criteria could best be promulgated using a frequency dependent approach. In support of this philosophy, the Air Force developed and published a new regulation in Nov 75., viz, AFR 161–42, Radiofrequency Radiation Health Hazards control. It incorporates, as a conservative first step, a slightly higher frequency dependent exposure level for the 10KHz to 10MHz portion of the RF spectrum, where no previous standard existed. It remains consistent with the OSHA regulation which covers the frequency range 10 MHz to 100 GHz. This new safety standard which defines a complete RFR hazards control program has been accepted throughout the Air Force and has been implemented by all major commands, since it provides detailed guidance on the application of PELs (permissible exposure limits) across the frequency range of AF RF emitters.

Research studies in support of 10–30 MHz RFR emitters (principally the OTH–B radar) were essentially completed this past year. Power absorption studies were completed for the 10–50 MHz frequency band and compared with theoretical calculations. These data have been published on monkeys, prolate spheroid and ellipsoid models. Primate temperature profiles, as a function of incident power densities and time, were completed for three HF band frequencies (15–20, 26 MHz). Power densities ranged from 500 to 1500 mW/cm^2 and exposure times from 0.5 to 6 hours. The previous studies on the effects of HF band radiation on rodent growth and development by SAM and its contractors were reevaluated and documented in SAM–TR–75–51. Air Force program interests are now directed to phased array radar systems using RFR fields in the frequency range 0.4–10 GHz.

Air Force contractual efforts in support of the Tri-Service ocular effects program resulted in the development of a system for noninvasive optical evaluation of RFR induced eye abnormalities. A follow-on contract was awarded to conduct bioeffects studies to evaluate the utility of the completed system. Pending successful validation, this new research tool may be applied to objectively quantitate possible effects of RFR induced eye injury in a series of experiments ranging from acute to long term exposures. It will also provide a permanent record for comparative purposes.

In order to study mechanisms of injury and perhaps reduce the use of animals a specialized exposure system for irradiating cell cultures to broadband RF fields under controlled field and temperature conditions was developed under AF contract with the University of Washington. The system produces a quite uniform electric field strength up to 10,000 V/m (over a frequency range 0–1000 MHz) for a 5 mm sample of culture medium. Preliminary experimental results have been reported. Additional research is in progress.

Microwave inactivation techniques sponsored/developed by the Air Force were used in four distinct and separate studies of RF radiation induced CNS effects. Mice were exposed to 19 MHz using a "near-field" radiation simulator to determine if HF band radiation alters the whole brain level of: (1) serotonin of its metabolite 5-hydroxyindole acetic acid; and/or (2) norepinephrine. Other studies were completed for rates exposed to 1600 MHz fields. Additionally, metal ion concentrations in specific areas of the rat brain were evaluated after 1600 MHz exposures.

A six-port vector voltmeter developed by the National Bureau of Standards under Tri-Service Precision Electromagnetic and Air Force funding and sponsorship has been completed and is in operation at the USAF School of Aerospace Medicine. This instrument is capable of measuring voltage ratio and phrase angle between any two given signals in the 500 MHz to 12 GHz frequency range. Applications of the system include measurement of coupling ratio for high power couplers, measurement of antenna transmittance and reflectance, and measurement of RF field changes induced by insertion of biological systems into an RF field. The system is controlled by an HP model 9830A and has a unique calibration capability.

Recent reports in the literature have indicated changes in the permeability of the blood-brain barrier after exposure to microwaves. Because of the serious safety implications of these reports attempts were made to replicate one of the investigations. In the reported study, 1200 MHz radiation pulsed at a low peak power density (2 mW/cm^2) was reported to increase the permeability of the blood-brain barrier to sodium fluorescein.

In the USAFSAM replication, fluorescence due to sodium fluorescein in the brain substance of irradiated rats was not observed at the peak power reported in the original investigation. The study was extended to include chemical assay of sodium fluorescein in various areas of the brain. At a peak power of 2 mW/cm^2 no increase in the brain concentration of sodium fluorescein was noted. However, at a peak power of 75 mW/cm^2 (37.5 mW/cm^2 average) the fluorescein content was significantly increased as compared to control. At this higher peak power level brain temperature was increased about 4°C. Further research is being carried out to establish a threshold for the increased fluorescein content. Additional studies will be initiated using radiolabeled compounds that do not normally cross the blood-brain barrier. It is strongly recommended that laboratories make a maximum effort to participate in replication of all important research findings.

A series of experiments was conducted to investigate the effects of radiofrequency radiation (RFR) heating on cell-mediated immune defense mechanisms. RFR heating effects, as determined by inflammation and/or the number of peripheral blood and spleen lymphocytes, were followed in rodents exposed to 26 MHz radiation (3° C increase in core temporature), 5 MHz (no measurable increase), and warm-air treatment (3° C increase). RFR heating (26 MHz) decreased SRBC-induced inflammatory footpad swelling by 45% over that observed in warm-air or sham control animals. The suppression of inflammatory response was accompanied by a well-defined, transient four-fold lymphopenia and neutrophilia maximal at 3 hours post-exposure. Normal blood lymphocyte and neutrophil levels were reestablished by 92 hours post-exposure. Triple exposure to 26 MHz radiation at 3-hour intervals achieved a marked, but transient lymphopenia and neutrophilia sustained over a 12-hour period; all animals reverted to normal level by 92 hours after the final exposure. Time course of this lymphocyte response closely follows glucocorticoid-induced lymphopenia and suggests that RFR heating is perceived as a simple stress phenomena accompanied by steroid release. In addition, percentage of T-lymphocytes in the spleens of RFR heated mice (26 MHz) was two-fold greater than that observed in 5 MHz, warm-air, or sham treated animals. That RFR heating induced an arrest in T-cell splenic traffic resulting in apparent pooling of T-lymphocytes in the spleen, in addition to suppression of inflammatory response and lymphopeneia, suggests that cell-mediated immunocompetence may be altered in these animals.

CFY + 2:	4	220 K

Project Summary: 12. Objective, 13. Approach

12. Objective: Investigate the effects of electromagnetic radiation (EMR) stress on immune systems. Specifically to determine the magnitude and direction, cause(s) and thresholds of EMR induced changes in immune responsivity. Also to establish nonputative thresholds for frequency and power dependency of continuous and pulsed wave EMR stress on immune function.

13. Approach: Quantitate, initially, RF induced changes in the ability of test animals to mount a viable *in vivo* cell-mediated immune response-cutaneous delayed hypersensitivity (DTH), to antigenic challenge. Subsequently to delineate through *in vitro* techniques effects of EMR stress on specific cell-mediated effector mechanisms operating in DTH.

14. Progress: Three strains of mice, C56Bl/6, CD-1, and B6D2F1, have been successfully sensitized to mycobacterium H37Ra and to the protein ovalbumin; subsequently vigorous delayed hypersensitivity reactions (as measured by footpad enlargement) were elicited to characterize normal responses in mice in preparation for RF exposure experiments. Studies of RF treated mice (26 MHz, 2000 mW/cm^2, causing a 2.5° C increase in animal rectal temperature) revealed a time-dependent inversion in the relative number of circulating segmented polymorphonuclear leukocytes (PMN) and lymphocytes (L): preexposure, levels within 24 hours. In addition, total leukocyte cell number was depressed at 6 hour postexposure by 25±4% (3564±104 versus 4760±150 cells/cc) over normal control values: this leukocytopenia was transient and normal cell count was observed 12 days after exposures. The above results were presented at the 1976 NRC/URSI meeting in Amherst MA, 11-15 Oct 76 (FY77).

Project Summary: 12. Objective; 13. Approach

12. Objective: Reports have appeared with increasing frequency which would indicate microwave exposure effects upon various components of the hematopoetic system, particularly the small lymphocyte. The frequencies and power levels used vary from study t study, but in general encompass areas which represent portions of the spectrum which include existing or planned Air Force systems. This study will attempt to define an RF effect on humoral antibody production, which, if it exists, would be of practical significance as far as the ability of exposed personnel to withstand infection and to develop effective immunity in response to the challenges in the environment.

13. Approach: Hybrid inbred mice will be exposed for prolonged periods (up to six wee to RF radiation at frequencies and power levels which are scaled to represent equivalent human exposure. Following exposure, an antigenic challenge will be made, and the response assayed by measuring the presence of splenic plaque forming cells. Where R effects can be detected, further study will try to define threshold levels, thermal vs non thermal characteristics, and relative efficiency for production of effects from CW or pulsed application over extended periods of time.

Current:	1.0	80K
CFY + 1:	0.0	0
CFY + 2:	0.0	0

Project Summary: 12. Objective, 13. Approach

12. Objective: Assessment of suspected or actual eye injury resulting from radiofrequency (RF) radiation exposure depends largely on subjective evaluations. The purpose of this project task is to develop a system to quantitate eye abnormalities for RF radiation personnel hazard assessment; specifically to conduct research and development resulting in a portable device (s) capable of both holographic recording and short pulse scattering measurements in the eye. The device is required to quantitate and study radiofrequency radiation-induced eye opacities.

13. Approach: Previous research conducted under a memorandum of agreement with the U.S. National Bureau of Standards and under AF contract with the University of Washington resulted in the development of two promising techniques for noninvasive optical evaluation of RF-induced cataracts in the eye in vivo. The first uses short pulse laser range-gating and scattering measurements to determine the thicknesses of ocular layers and the second records holographically the 3-dimensional internal structure of the eye including microcataracts. These techniques will be incorporated into a system which can be used to quantitate eye changes and produce permanent records of such changes.

14. Progress: Construction of system has been well detailed and assembly of final system has begun. Problems associated with holographic phase coherence were overcome by proper laser cavity loading. Coherence length is approximately 3 cm. Adaptation of fiber optic pickup to range-gated laser pulses demonstrated very good fit to a Mie scattering curve with particle sizes down to 5 μ or less. Completion of Vidicon imaging of Kerr cell range-gate was accomplished, giving range resolution of 1 mm or less without treatment of raw data. Demonstration of particle size distribution in microwave cataracts was accomplished in July 1976.

Current:	4	180K
CFY + 1:	4	200K
CFY + 2:	4	210K

Project Summary: 12. Objective, 13. Approach

12. Objective: The objectives of this work unit are to develop equipment and methodology and to perform the experiments necessary to define radiofrequency (RF) energy transfer to animals and man. The results of these experiments will continue to provide the basis for modifying the personnel exposure criteria for Air Force RF operations.

13. Approach: Instrumentation will be developed to monitor incident fields and absorbed power for biological systems exposed to RF fields in the range of operational AF systems, namely 10 MHz to 10 GHz. Present power absorption techniques are usable from 10 to 50 MHz. Methodology will be developed to measure power absoprtion in the 50 MHz to 10 GHz frequency range. Modeling of animals will continue until a suitable model is found and this model will be used to perform the theoretical analysis necessary to predict power absorption over the frequency range of concern.

14. Progress: Differential power measurements were completed for 20 ellipsoid phantoms, designed to represent the sitting rhesus monkey, and for 20 live monkeys exposed to 10, 20, 30, 40 and 50 MHz RF fields. The phantoms were filled with saline solutions with conductivities of .054, .245, .36, .54 and .64 mho/m. Phantoms and monkeys were measured for six orientations. A new read-out technique was devised using an HP 9830A programmed to read the input, reflected and output power and compute differential power. This technique improved the accuracy of measurement as well as reducing the time required for this set of measurements by a factor of three. Comparison of the power absorbed by the live monkeys was within ± 10% of previous tests.

CFY + 2:	2	70K

Project Summary: 12. Objective, 13. Approach

12. Objective: The setting of safety standards for electromagnetic radiation (EMR) for AF personnel must rest on a foundation of known bioeffects of this type of radiation. The objective of this effort is to investigate radiofrequency (RF) field effects in biophysical model systems. The information gathered will allow the adjustment of exposure criteria for AF personnel working in unique RF radiation environments.

13. Approach: Field modulation effects, including pulsed fields, on a variety of central nervous system (CNS) ionic and chemical distributions will be examined. The effects of EMR fields on solvent transport processes in tissue and polarization processes in macromolecules will also be investigated. An attempt will be made to relate alterations in the trace metal content in various areas of the rat CNS with frequency, power density and thermal stress, and to extrapolate these findings to an expected effect on AF personnel operating in EMR environments.

14. Progress: Trace metal determinations in rat brains are continuing. Current effort nearing completion, utilizes exposure levels calculated not to produce a detectable CNS temperature rise in an attempt to determine an RF exposure threshold for changes in divalent metal ion metabolism. Studies have been completed in which core temperature rise as a function of frequency and power was observed in monkeys exposed for 180 minutes to HF band frequencies. See SAM-TR-76-20 and subsequent report in press.

Project Summary: 12. Objective, 13. Approach

12. Objective: To establish a biomedical data base on the interaction of Air Force radiofrequency (RF) radiation emitters and medical prosthetic devices. To maintain a state-of-the-art technology watch on cardiac pacemaker interference. Assess manufacturers' progress in developing pacemakers to operate properly in pulsed RF fields of 200 rms volts per meter. Apply data to operational situations in accordance with AFR 161-42.

13. Approach: New state-of-technology pacemakers will be accepted on loan from device manufacturers and evaluated under a variety of RF emission sources in the USAFSAM laboratory. Sources will include radiofrequencies between 10-500 MHz. Field tests will also be conducted using an HF band transmission system at AVA NY in support of the CONUS OTH PO. Additional field tests will be conducted in support of specific operational problems as provided by AFR 161-42.

14. Progress: Cardiac pacemaker interference data were completed for radiofrequencies of 450, 1600, and 3200 MHz. These results along with summaries of expected effects from several types of radar and other special AF emitters were published in SAM-TR-76-4, "The biological significance of radiofrequency radiation emission on cardiac pacemaker performance," Jan 76. Pacemaker risks criteria were provided HQ USAFE/SG, USAF Hosp Wiesbaden/SGPM, ESD/OCN, and USAF Hosp Lindsey AS GE/SGPM for a series of operational RF emitters. A series of new generation cardiac pacemakers was evaluated under both free-field and simulated implant conditions for radiofrequencies of 250, 350, and 450 MHz. Potential susceptibility levels in rms volts per meter were established for pulse widths of 10 μsec, 1 msec, and 20 msec at 5 and 10 pulses per second. A summary report is in preparation. These data will be provided to the USAF/SG. Consultations concerning EMI risks criteria were provided for the AN/MST-T1, AN/MPN-13, AN/GPS-10, AN/FPS-7, AN/FPS-90, and to other operational systems as requested.

CFY-1:	3	90K
Current:	4	120K
CFY + 1:	4.5	135K
CFY + 2:	5.0	150K

Project Summary: 12. Objective, 13. Approach

12. Objective: The Department of Defense Triservice electromagnetic radiation (EMR) bioeffects research program describes the central nervous system (CNS) as the "singularly most important area where there is evidence that EMR interacts with biological systems." The objective of this effort is to quantitate the radiofrequency (RF) EMR effects on biochemical events subserving nerve transmission in the CNS. The information obtained will be applied to establish more appropriate safety standards for personnel working in close proximity to AF RF emitters.

13. Approach: The effects of RF radiation on the CNS, specifically on a specialized function of the neuron, namely synaptic transmission will be studied. It is probably true to say that every cell in the brain is connected, directly or indirectly, to every other cell by chemical switching systems (synaptic transmission). This effort will attempt to quantify changes produced by RF energy in these chemical systems, determine thresholds for frequency and power density, and interpret these changes in terms of the expected effect on man in AF operational environments.

14. Progress: Temperature profiles for core and brain of rats exposed to 1600 MHz radiation have been obtained. Both brain and core temperature increases are related to the orientation of the animals' long axis in the radiation field, i.e., when the long axis of the rat is parallel to the electric component, the rectal temperature was greater than when the animals' long axis was oriented to the magnetic component. Neurochemical studies show that the neurotransmitters norepinephrine and dopamine are decreased in the hypothalamus of animals whose brain temperatures had been elevated above 5° C by the radiation. An apparent increase in the rate of biosynthesis of the neurotransmitter serotonin, possibly as a result of the increase in temperature of the tissue in the midbrain was noted.

9. Frequency(ies): 10 kHz-10 GHz

10. Exposure Range: 1-100 mW/cm^2 equivalent man exposures

11. Resources:

Year	a. Manyears	b. Funds
CFY-1:	0.5	115K
Current:	1.0	130K
CFY + 1:	1.5	150 K
CFY + 2:	1.0	190 K

Project Summary: 12. Objective, 13. Approach

12. Objective: The highest priority task in the DOD triservice electromagnetic radiation (EMR) bioeffects research program is to develop better methodology for quantitating EMR energy distribution and measurement. Methods and data are critically needed to extrapolate (via appropriate scaling factors) animal data to man and thus to establish more realistic personnel safety exposure guidelines for AF operations. The specific objectives of this study are (1) to define adequate models, (2) to extend theoretical radiofrequency (RF) power absorption data to assess consequences of man's exposure to 10 kHz to 10 GHz RF radiation fields, and (3) to develop methods, accounting for size and orientation effects, to extrapolate animal exposures to equivalent human exposures.

13. Approach: Twenty phantoms (models) will be constructed to best represent 3.5 kg monkeys. Absorbed power per kg will be calculated utilizing this monkey model for exposures in free space, near field and on a ground plane. Experiments will be conducted to measure power absorbed in the phantom and in actual monkeys for six exposure orientations. The best model for man, monkey, rat and mouse will be developed and calculations performed to determine power density to which these animals should be exposed to produce the same average absorbed power as man when exposed to 10 mW/cm^2 at the same frequency. The exposure frequency for animals subjected to the same power density as man to accomplish equivalent average power absorption will also be calculated. These data will be used to compile an RF Dosimetry Handbook for use in selecting appropriate exposure parameters (frequency and power density) for animal studies to simulate bioeffects in man. Power absorption calculations for man and animals will be extended using wave solution, numerical techniques, or other applicable methods.

Title: Comparison of Theoretical and Experimental Absorption of RF Power (77570152)

14. Progress: Twenty ellipsoid phantoms averaging 3.4 kg were constructed and shipped to the USAF School of Aerospace Medicine. These phantoms were 40 cm in length and the b/c ratio was 1.5. A new molding technique produced a seamless phantom. The radiofrequency radiation handbook was completed and published as SAM-TR-76-35. This document (first edition) provides predictions of specific absorbed power for 14 animal species to aid experimenters in evaluating experimental results and equating such results to equivalent human exposures. About 200 copies were distributed at the 1976 IEEE/URSI meeting. An annual update is planned.

6. Performing Organization and Address:
University of Washington
Seattle, Washington

a. Principal Investigator:
A. W. Guy

7. Start Date: 1174

8. Estimated Completion Date: 0877

9. Frequency(ies): 20-10,000 MHz

10. Exposure Range: 1-1500 mW/cm^2

11. Resources:

Year	a. Manyears	b. Funds
CFY-1:	0.5	115K
Current:	1.0	145K
CFY + 1:	1.0	160K
CFY + 2:	1.0	185K

Project Summary: 12. Objective, 13. Approach

12. Objective: Extend current energy distribution and measurement methodology using thermographic techniques to more accurately assess RF power deposition in scaled models of man. Determine the thermal load and RF fields in tissue which produce such loads, and determine the rate at which the tissue thermal loads are dissipated. Measure some of the bio-responses to such insults in the frequency range 20 MHz-10 GHz.

13. Approach: Scale models of man will be exposed to 720-980 MHz plane wave fields to simulate the exposure of a full scale man to the high end of the HF band through the UHF band frequency range. Power absorption patterns will be obtained for animals exposed to 0.143, 7.50, 9.14, 2.450, 3.3, and 9.0 GHz at the University of Washington and 0.45, 1.3, 1.6, and 6.0 GHz at SAM. Heat flux equations for locally deposited thermal loads will be developed. Cell culture studies will be initiated.

Continued ....

Title: Measurement of Power Absorption at Resonant & Nonresonant Frequencies (77570149)

14. Progress: An exposure system has been developed for exposing cell cultures to broadband electromagnetic fields under controlled field and temperature conditions. This system can produce a reasonably uniform electric field strength up to 100 V/cm in a 5mm sample of culture medium with system input powers up to 600 W over a frequency range 0-1000 MHz. Temperature control and measurement can be achieved at frequencies up to 100 MHz by the dependence of feedline impedance on culture medium temperature. Steady-state temperatures below 37° C can be maintained with CW exposure of the cultures at field strengths in excess of 25 V/cm. In preparation for in-vitro exposures of cultured primate lymphocytes, preliminary determination of the requisite biological parameters were established and results from initial lymphocyte exposures were documented. A statistically valid (p less than 0. 01, Chi square test) inhibition of cell division was found on exposure of lymphocytes to fields of 5 volts cm^{-1} under very carefully thermostated conditions with gas atmosphere controlled and with simultaneous controls run in normal culture vessels, or in the radiator in the absence of power. Exposures were at 20 MHz. These correspond to fields of several hundred volts/meter external to an experimental animal or man.

APPENDIX B

NO COMMENTS

APPENDIX C

NO COMMENTS

APPENDIX D—CRITERIA AND/OR STANDARDS DEVELOPMENT—IONIZING AND NON-IONIZING RADIATION

Provided under this heading are resources expended by the Air Force in publishing required implementing directives to place the requirement of newly enacted laws, executive orders and federal guidelines into the Air Force management system. In order to insure understanding and compliance with a given law, it is necessary to assign responsibilities and provide mechanisms for accomplishing the specific requirements of the law within the Air Force organizational framework.

When federal guidance has not been promulgated, but a need exists within the Air Force, criteria or standards are developed based on national consensus standards or Air Force conducted/sponsored research on the particular subject area. These resource expenditures are also included under this heading.

Specifically, in 1971–72, the AMD/USAFSAM conducted necessary studies and formulated human electromagnetic pulse (EMP) safety criteria to support EMP tests of the Minute Man II weapon system. These criteria were reviewed and updated in 1974 and appropriate material was provided to the Office of Standards OSHA–DOL. The work identified during 74–77 involved HF band data analysis and the publication of AFR 161–42 RFR Health Hazards Control.

APPENDIX E—STATE/FEDERAL LIAISON—IONIZING AND NON-IONIZING RADIATION

Included in this heading are resources expended maintaining liaison with federal agencies. Liaison is maintained with states at the local installation level in the areas of radiation health effects out of professional courtesy. Liaison with other federal agencies is maintained through Air Force participation in federal/interagency working groups and committees; through participation in interagency programs such as the BRH's Nation-wide Evaluation of X-Ray Trends Program, and through the formal mechanisms of replies to published notices for information or rulemaking in the Federal Register.

APPENDIX F—LICENSING AND INSPECTION

IONIZING RADIATION (LICENSING AND CERTIFICATION)

The Air Force Medical Materiel Field Office (AFMMFO) manages a program for acceptance testing maintenance and periodic inspection of diagnostic x-ray systems. The AFMMFO was officially organized in 1957 and has had primary responsibility for the program since that date. As a part of its mission, AFMMFO promulgates internal Air Force directives concerned with the calibration, maintenance, and acceptance of diagnostic x-ray systems and other medical devices. The implementing regulations issued by the Food and Drug Administration in accordance with PL 90–602, required changes in maintenance, calibration, and acceptance procedures. Procedural changes which were adopted during 1975 were made to insure that equipment system purchased and maintained by the USAF remained in compliance with the intent of PL 90–602. This action resulted in an initial capital investment for specialized test equipment of an estimated $58,000 and a 12% increase in workload associated with the maintenance, calibration, and acceptance of diagnostic x-ray systems. This workload is spread over some 116 different locations throughout the world and equates to an estimated 6 manyears. In addition, an estimated 1 manyear is used in central program management and training of Air Force technicians.

Positive Air Force control over the use of all radioactive materials in the Air Force has been assured through the establishment of a Radioisotope Committee. This committee acts as the single point of Air Force contact with the US Nuclear Regulator Commission for radioisotope licensing matters, and oversees the use of radioactive items maintained on the Air Force license.

IONIZING AND NONIONIZING RADIATION (INSPECTION)

Compliance with Air Force directives and federal law Air Force-wide is assured through the inspection activities of the Air Force Inspector General (IG). The Air Force IG acts as an internal inspection and audit agency for the Air Force and identifies deficiencies or noncompliance with Air Force directives or federal laws to responsible commanders throughout the Air Force chain of command. Through Air Force-wide inspections of installations both local deficiencies and Air Force-wide program weaknesses are identified for corrective action.

APPENDIX G—MONITORING AND/OR SURVEILLANCE

IONIZING AND NONIONIZING RADIATION

As part of the overall Air Force Occupational Health Program, routine field surveys of radiation sources/emitters and evaluation of administrative and engineering controls to assure personnel safety are made by local installation personnel. Remote sites receive consultant support from "attending" personnel from larger installations. Where additional equipment, analytical, or personnel requirements exist that are beyond the capability of local installations, consultant support is provided by designated laboratories or specialized teams. The USAF Occupational and Environmental Health Laboratory provides equipment loan, analytical capability and field consultant and measurement service Air Force-wide on health related problems resulting from both ionizing and non-ionizing radiation. The Air Force Communications Service provides field measurements and consultant service for health hazard evaluation and for electromagnetic interference.

Adequate instrumentation for almost all routine monitoring of ionizing radiation sources has been available and maintained at local installations since well before 1968. As manufacturers have improved their instruments, upgrading of instrumentation has been accomplished. Workload for surveillance of ionizing radiation sources at the local installation level has remained fairly constant. In the case of non-ionizing radiation, lack of simple, rugged hand-held field survey meters severely limited measurements by the local installation. Consequently, monitoring and surveillance of non-ionizing radiation emitters was minimal. The development and introduction of hand-held, broad band survey instruments into the Air Force has significantly improved our capability.

The continued introduction of such instrumentation, as well as the development of new technology, will create an increasing commitment of resources to monitoring non-ionizing radiation.

APPENDIX H

No Comment

APPENDIX I—COLLECTION AND ANALYSIS OF HEALTH DATA

IONIZING AND NON-IONIZING RADIATION

Epidemiologic studies of persons exposed to radiation are not conducted except when an accident or potential overexposure may have occurred and medical data is collected as part of the investigation to determine if any clinical change was incurred as a result of the exposure.

IONIZING RADIATION

The USAF Occupational and Environmental Health Laboratory provides centralized dosimetry and bioassay services for individual occupational exposure to ionizing radiation. These data are reflective of personnel "health" in that they provide a data base for evaluating "population at risk" exposure levels. Resources shown are essentially those involved with the operation of the USAF Personnel Dosimetry Program including film and thermoluminicent dosimeter processing, record keeping, and radiation exposure control.

NON-IONIZING RADIATION

Positive physical examinations are not considered to be required for occupational exposure below the established PEL's and practical personnel dosimetry has not been demonstrated. Hence, there are no data entries for non-ionizing radiation.

APPENDIX J

No Comments

APPENDIX K—OTHER BIOLOGICAL OR PHYSICAL EFFECTS STUDIES

Reports of electromagnetic interference (EMI) of life sustaining cardiac pacemakers prompted the Chief of Staff, USAF, and the Surgeon General, to direct a study to evaluate all USAF radar and RFR systems. Data were acquired on EMI effects on all major US and West European pacemakers and results were made available to the US Food and Drug Administration and appropriate pacemaker manufacturers. This has resulted in major design changes and improvements in pacer manufacture. Wrap up studies and technology watch efforts will continue in 1977, terminating in 1979.

APPENDIX L

NO COMMENTS

DEPARTMENT OF THE ARMY,
OFFICE OF THE SURGEON GENERAL,
Washington, D.C., June 9, 1977.

Hon. WENDELL H. FORD,
Chairman, Consumer Subcommittee,
U.S. Senate,
Washington, D.C.

DEAR SENATOR FORD: General Taylor has asked me to reply to the letter signed by you and Honorable Adlai E. Stevenson on 20 May 1977 concerning federal radiation research and regulatory programs. I am also sending Senator Stevenson an identical letter.

Information in the matrices is the best estimate of funds expended and in-house man year performance for the US Army Medical Research and Development Command (USAMRDC) and the US Army Environmental Hygiene Agency (USAEHA) during the ten year period requested.

The ionizing radiation project to develop a chemical protector against fallout was terminated during fiscal year 1973. The microwave research program was transferred from the Defense Advanced Research Project Agency (DARPA) to USAMRDC during fiscal year 1972. Laser research was formerly conducted as a joint project between the Army Materiel Command (AMC) and The Surgeon General until fiscal year 1975, when this joint effort was terminated. At that time, USAMRDC initiated a separate laser effects project.

The Office of the Director of Defense Research and Engineering (ODDRE) is consolidating the answers to the four questions and submitting a separate reply.

Sincerely,

ROBERT W. GREEN, M.D.,
Major General, MC,
Acting The Surgeon General.

MICROWAVE

1. *Studies to determine human health effects.*—All studies conducted in this program have been designed to ascertain human health effects but have been conducted using laboratory animals, phantom models or animal tissues. No human subjects research has been conducted. The research program supported by funds shown here include:

(*a*) Microwave energy absorption and distribution in experimental animals and manikin models.

(*b*) Microwave effects on nervous and sensory systems.

(*c*) Microwave effects on behavior and performance.

(*d*) Stress reaction resulting from microwave radiation.

(*e*) Dosimetry for recording and evaluating microwave radiants.

2. *Other biological or physical effects.*—These studies support neuropsychiatric research programs in biochemical analysis and enzyme inactivation.

3. *Other studies.*—Funds here have been used to develop and maintain a comprehensive data base of world literature related to biological effects of electromagnetic radiation. This has been a joint effort of several federal agencies and in FY 77 has been assumed by the Office of Telecommunications Policy.

4. All other columns are not applicable to the Army medical department research program.

LASER

1. *Other biological or physical effects studies.*—All studies have been conducted utilizing laboratory animals, phantom models or animal tissue. Data generated are to be used to extrapolate human health effects of laser radiation. No research has been conducted on human subjects. Laser research is conducted in the following areas:

(a) Ocular effects of laser radiation.

(b) Behavioral effects of laser irradiation.

(c) Laser effects on skin and cutaneous tissue.

Primary research is conducted with three laser frequencies: carbon dioxide, gallium arsenide and neodymium.

2. *Other studies.*—This program was designed to develop specialized instruments for use in the study of biologic effects of laser radiation. The information in this column could have been entered in Column 1, but since research was not conducted on human subjects, it seemed appropriate to consider it as other biological effects. All final data is used to extrapolate effects to the human, however.

3. No other column on the matrix is applicable to the Army medical department laser research program.

IONIZING RADIATION

1. The Army medical department program in ionizing radiation was designed to develop a chemical means of protection against the effects of ionizing radiation. Primarily, the purpose was directed at protection against Beta and Gama radiation resulting from nuclear weapons employment and fallout resulting from nuclear weapons detonation.

2. *Other biological and physical effects.*—The research conducted was for the synthesis of new chemical structures which might provide protection against radiation. Biological screening of these chemicals as well as other chemical substances was conducted on small animals, primarily rodents, and on primate models to determine efficacy of the chemicals. In addition to these projects, research was conducted, using human subjects, to determine tolerance to the chemicals. No human subjects were exposed to radiation.

3. *Other studies.*—Two studies were conducted. One was a study, using an operational scenario, to determine the usefulness of chemical protection; but it was inconclusive. The second study involved ad hoc committees looking at three aspects of the therapy of radiation injury: immunologic aspects, early indicators and metabolic aspects. The information in this column could have been entered in Column 1, but since research was not conducted on human subjects, it seemed appropriate to consider it as other biological effects. All final data is used to extrapolate effects to the human, however.

4. No other columns on the matrices are applicable to the Army medical department ionizing radiation research program.

BRIEF DESCRIPTION OF USAEHA ACTIVITIES IN THE PROJECTS LISTED ON THE MATRIX DATA SHEETS

1. Studies to Determine Human Health Effects: Ocular effects surveillance.

2. Ecological Efforts, Animal/Plant: NA

3. Agricultural Effects, Plant/Animal: NA

4. Criteria and/or Standards Development: Preparation of DA standards documents and participation in national standards committees such as those of the American National Standards Institute.

5. State/Federal Liaison: Liaison and coordination with State and Federal agencies such as the Bureau of Radiological Health, the Department of Labor, the National Institute of Occupational Safety and Health, the US Environmental Protection Agency and the Nuclear Regulatory Commission.

6. Licensing, Certification, Inspection: Review of Nuclear Regulatory Commission license applications, DA authorizations, certification training of DA personnel, and participation in formal general inspections.

7. Monitoring and/or Surveillance: Activity/installation radiation protection surveys, equipment special studies and evaluations, and evaluations of radioactive commodities.

8. Medical Diagnostic, Therapeutic: That portion of the ionizing and nonionizing radiation protection programs applicable to these medical devices.

9. Collection and/or Analysis of Health Data: Analysis of samples collected from personnel occupationally exposed to radioactive material.

10. Collection and/or Analysis of Environmental Data: Analysis of environmental samples for compliance with air and water quality standards.

11. Other Biological or Physical Effects Studies (Explain): NA

12. Other Studies (Explain): Training in all aspects of radiation protection conducted by this Agency.

DEFENSE ADVANCED RESEARCH PROJECTS AGENCY,
Arlington, Va.

Hon. ADLAI E. STEVENSON,
Chairman, Science, Technology and Space Subcommittee, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR SENATOR STEVENSON: Thank you for your letter of May 20 requesting information relating to radiation health and safety research. During the perod from 1965 to 1971 we supported Project Pandora which was concerned with reviewing the safety levels associated with microwave radiation, and I have enclosed a summary of this project.

Since the programs of our Agency are directed toward advancing technology for future military systems, we do not normally support research associated with radiation health and safety. In the future, we do not plan to undertake programs in the area of radiation health and safety research, and the specific questions you pose are not ones to which we can contribute meaningful information.

I hope this information will be helpful to you and the members of the committee.

Sincerely,

GEORGE H. HEILMEIER,
Director.

NON-IONIZING RADIATION

HUMAN HEALTH EFFECTS

Title: Project Pandora.

During the period 1965–1971 Defense Advanced Research Projects Agency sponsored Project Pandora which was concerned with the biological effects of microwaves and investigated the adequacy of established safety levels for normal working exposure to radio frequency radiation. When it became apparent that established U.S. standards for radiation exposure were adequate and that no new effects could be observed, the project was terminated.

Funding:

Fiscal year 1968	$925,000
Fiscal year 1969	464,000
Fiscal year 1970	367,000
Fiscal year 1971	200,000

DIRECTOR OF DEFENSE RESEARCH AND ENGINEERING,
Washington, D.C.

Hon. ADLAI E. STEVENSON,
Chairman, Science, Technology and Space Subcommittee,
U.S. Senate, Washington, D.C.

DEAR SENATOR STEVENSON: This is in response to your joint letter with Senator Wendell H. Ford of 20 May 1977 concerning federal radiation research and regulating programs. I understand that the individual Military Surgeons General were also requested to respond on this subject and my staff has coordinated this response at the working level to avoid providing you duplicative information. Specifically, the Services will supply the detailed matrix data requested by your enclosure, since these data represent the total of the DoD effort. Attachment 1 contains my response to the four questions posed. Each Surgeon General may provide supplemental answers in areas of unique Service concern.

Should additional information be required, please contact me. I will be pleased to designate a witness to testify for all DoD at the hearings in June if you so desire.

Sincerely,

WILLIAM J. PERRY.

Attachment.

Responses to questions posed by Committee on Commerce, Science and Transportation, U.S. Senate regarding federal research and regulatory programs.

Question (1) What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Response (1) There have been numerous changes in federal agency jurisdiction on the control of ionizing and non-ionizing radiation health hazards that have impacted DoD programs, and in varying degrees increased our overall efforts. Most notable are: the enactment of PL 90–602 which established electronic product emission standards; the enactment of PL 91–190, the National Environmental Policy Act which requires all federal agencies to assess their proposed or continuous actions for environmental consequences; the President's reorganization Plan #3 establishing the Environmental Protection Agency (EPA) and transference of the Federal Radiation Council functions to the EPA; and the establishment of the Office of Telecommunications Policy (OTP) which formed the Electromagnetic Radiation Management Advisory Council (ERMAC) to advise on possible side effects and the adequacy of control of electromagnetic radiations associated with use of the electromagnetic spectrum. The Defense Department has a high degree of awareness of the potential health hazards associated with the development of weapon systems that emit electromagnetic radiation. Definitive measures have been instituted early in the systems acquisition phase to eliminate emissions that are not necessary for weapon system effectiveness. The most significant action resulting from changes in federal policy has been the ERMAC's initiation of a multi-agency federal government effort to evaluate the effects that electromagnetic radiation has on living organisms under different exposure conditions, determine the clinical significance of these data, assess the hazard associated with any observed effects and establish a rational scientific basis and guidelines for developing appropriate control measures. The DoD has participated in this interagency activity maintaining a full awareness of other federal agency research programs. Through this cognizance, unnecessary duplication is avoided and the data generated is shared by all.

Question (2) Would you please describe the nature of the contacts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and federal agencies?

Response (2) There is no required formalized contact with the states with regards to occupational radiological health matters since under OSHA, the states have no primacy over federal activities even when the states have an approved program. This is also true with respect to use or radionuclides under an NRC license vis-a-vis agreement states.

In the area of environmental quality, the DoD is bound to comply with federal or state and local requirements, whichever are more stringent. The formal interface with state and local agencies is accomplished by each military installation through the regional office of the EPA. Again, as a matter of professional courtesy, interchange with state offices is encouraged by DoD in areas of mutual interest. Confusion concerning respective responsibility where it has existed has been readily resolved to date.

Question (3) Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved. Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Response (3) The existing federal radiation regulatory programs could be significantly improved if the jurisdiction of each federal agency having regulatory authority was more clearly defined. The Department of Labor (OSHA), the Environmental Protection Agency, the Nuclear Regulatory Commission, and the Food and Drug Administration (BHR and BMD) each have legislative authority apparently with some overlapping areas of responsibility. Priority attention to this matter would prevent confusion in the future when new non-ionizing radiation standards are proposed.

Another factor which bears attention is the lack of consistency between standards proposed by the regulatory agencies. Any electromagnetic radiation product emission, occupational or environmental standard, must be consistent with all other standards based on reliable research data and capable of withstanding peer review. There is a growing tendency amongst the federal agencies controlling radiation hazards to propose standards in the absence of reproducible data demonstrating clinically significant effects or reliable epidemiological data that suggests the current standards are not safe.

Regarding funding levels, the increased interest in the effects of exposure to non-ionizing radiation has prompted the DoD to review its bioeffects research program and develop a tri-Service research plan. The plan assures that each

Service's research program complement each other, are responsive to weapon system requirements under development and identify resources needed to accomplish the program objectives. The DoD has initiated a program with congressional approval to increase the technology base funding which should provide the additional resources needed to enhance the bioeffects research program.

Question (4) What is your reaction to the proposals to consolidate all federal radiation activities into one federal radiation agency?

Response (4) Superficially, it might appear that a consolidated federal radiation agency tasked with all research and regulatory responsibility is the proper solution to the apparent confusion in this area. However, removal of defense systems biomedical research from DoD would be detrimental to the timely development of weapons systems. Also, there is a hazard of conflict of interest in any single agency being responsible for basic research, technology development as well as regulatory activity. Congress recently separated the former Atomic Energy Commission into two separate agencies, apparently for this reason. I believe that explicit delineation of regulation responsibilities by Congress amongst the existing federal agencies would promote harmony in this area, produce scientifically valid regulations, and properly protect the public.

Defense Nuclear Agency,
Washington, D.C., June 3, 1977.

Hon. Wendell H. Ford,
Chairman, Consumer Subcommittee,
U.S. Senate, Washington, D.C.

Hon. Adlai E. Stevenson,
Chairman, Subcommittee on Science, Technology and Space, U.S. Senate, Washington, D.C.

Dear Senators: I am pleased to respond to your letter of inquiry dated 20 May 1977. Enclosed is information furnished by Colonel LaWayne R. Stromberg, Director of Armed Forces Radiobiology Research Institute (a component of the Defense Nuclear Agency), on the Biomedical Research Program in Ionizing and Nonionizing Radiation of the Defense Nuclear Agency.

If you require any further information, please contact me or Colonel Stromberg at any time.

Sincerely,

R. R. Monroe,
Vice Admiral, U.S. Navy.

Defense Nuclear Agency,
Armed Forces Radiobiology Research Institute,
Bethesda, Md., June 2, 1977.

Hon. Wendell H. Ford,
Chairman, Consumer Subcommittee,
U.S. Senate, Washington, D.C.

Hon. Adlai E. Stevenson,
Chairman, Subcommittee on Science, Technology and Space, U.S. Senate, Washington, D.C.

Dear Senators: We are pleased to provide the information you requested concerning our radiation research program and to comment on the questions asked in your letters of 20 May 1977 to this Institute and to VADM R. R. Monroe, Director, Defense Nuclear Agency.

The Armed Forces Radiobiology Research Institute (AFRRI) was chartered in 1962 to study the biomedical effects of ionizing radiation using sources that would simulate in dose and type that released by the detonation of a nuclear weapon. The present charter, dated 11 May 72 (Incl. 1), defines the AFRRI role in the Department of Defense and its relationship to the nonmilitary scientific community.

RDT&E funding is received from the Defense Nuclear Agency (DNA, formerly the Defense Atomic Support Agency). No operation and management funds are utilized in fulfilling the AFRRI mission. The current DNA Program Definition shows the AFRRI budget as funding element 6.27.04H, entitled "Biomedical Effects." Reimbursable authority to accept non-Defense Nuclear Agency funds is currently $800,000 for FY 77. Incl 2 gives a chronological history of funding and man-years spent on research in ionizing radiation effects. Research into nonionizing radiation effects including work to meet DOD requirements not directly related to nuclear weapons effects was instituted in FY 74. The effort in this area is summarized in Incl 3. This work includes research on the biological effects of exposures to extremely low frequency electrical fields and to microwaves to meet requirements of the U.S. Navy.

With regard to specific questions in your letter, the following comments reflecting the opinions of the AFRRI staff are offered:

Question 1. What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Comment. The primary changes have been the establishment of the Environmental Protection Agency, the implementation of the Occupational Safety and Health Act, the separation of the Atomic Energy Commission into the Energy Research and Development Administration and the Nuclear Regulatory Commission and the transfer of the Federal Radiation Council activities to the Environmental Protection Agency. The overall effect has been to increase the complexity and expense of meeting routine as well as special requirements generated by these different agencies due to the promulgation of additional regulations and a substantial increase in required reports. Since a particular program may well require coordination with several agencies, it may be necessary to seek agreement among agencies that have conflicting goals and viewpoints.

Question 2. Would you please describe the nature of the contacts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and federal agencies?

Comment. Our contact with state groups is minimal and is concerned primarily with coordinating emergency planning procedures and responses. This is a relatively simple matter and is not a source of significant confusion or difficulty.

Question 3. Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved. Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Comment. The present regulation of radiation programs tends to emphasize compliance with detailed regulations covering records keeping and maintenance of documents rather than the actual day-to-day operations. The emphasis of investigations and inspections should be less on detail and more on substantive operational issues.

An additional deficiency that we feel is critical does not relate directly to the regulatory process but has resulted from some of the reorganizations and realignments of functions that have occurred. This is the fact that there is now a critical lack of training courses in radiation safety. At one time the Bureau of Radiological Health sponsored a comprehensive and very valuable series of courses that helped materially in maintaining high standards of operating efficiency and safety. With the transfer of this function to the EPA, a severe deficiency has developed which has only been partially filled by the use of academic and commercial resources.

Question 4. What is your reaction to the proposals to consolidate all federal radiation activities into one federal radiation agency?

Comment. We feel strongly that a single federal radiation agency responsible for all federal radiation activities should not be formed. In the area of occupational health and safety, radiation is only one of many hazards and is frequently the least important. In medicine and in research, radiation is almost invariably one of the tools used to solve problems and not the basic reason for the research. In certain limited areas, radiation by itself is the fundamental factor, and these areas are quite properly the concern of a highly specialized agency such as the Nuclear Regulatory Commission which has a relatively narrow and well-defined charter. The problem with consolidating all federal radiation activities into one agency is that it would have to cut across too many disciplines and activities, and would require extensive duplication of existing expertise within other organizations.

Radiation problems should be maintained in their proper context and relationship to other problems, and dealt with appropriately by agencies with overall responsibilities or occupational health, environmental quality or medical research, such as the Department of Labor, the Environmental Protection Agency, and the National Institutes of Health, etc. In that way, a proper perspective and relative sense of value can be maintained. That areas of overlapping responsibility and controversy exist is true; however, these can be resolved with time if reasonable opportunity for open debate and discussion between agencies is provided.

I hope the above information is helpful. Should additional material be required, please contact us.

Sincerely,

LAWAYNE R. STROMBERG, MD.,
Colonel, U.S. Army,
Director.

Enclosure.

DEPARTMENT OF DEFENSE DIRECTIVE NO. 510S.33 MAY 11, 1972

Subject: Armed Forces Radiobiology Research Institute (AFRRI)
Reference: (a) DoD Directive 5105.31, "Defense Nuclear Agency (DNA)," November 3, 1971
(b) DoD Directive 5105.33, "Armed Forces Radiobiology Research Institute (AFRRI)," November 20, 1964, (hereby cancelled)

I. GENERAL

A. Established pursuant to the authority vested in the Secretary of Defense the Armed Forces Radiobiology Research Institute (AFRRI) is designated a subordinate unit of the Defense Nuclear Agency (DNA).

B. AFRRI shall serve as a radiobiology research laboratory for the Department of Defense. Other federal and civilian agencies and institutions may utilize AFRRI services as agreed upon by the Secretary of Defense or his designee.

II. MISSION

The mission of AFRRI shall be to conduct scientific research in the field of radiobiology and related matters that are essential to the medical support of the Department of Defense.

III. ORGANIZATION

A. AFRRI shall consist of a Director, a Deputy Director, and a supporting staff.

1. The Director, AFRRI will be a medical department officer in Grade 0–6 nominated by the appropriate Service and appointed by the Director, DNA after consultation with the Board of Governors. Normally, the position of Director will rotate among the Services. His tour of duty shall be consistent with professional and military requirements and applicable DoD Directives and Instructions.

2. The Deputy Director will be an officer in Grade 0–6 or 0–5 from one of the Military Services not represented by the Director.

3. The staff shall be constituted of military and civilian personnel authorized by a Joint Table of Distribution (JTD), developed by the Director, DNA, and approved by the Joint Chiefs of Staff. Insofar as possible, the military members of the supporting staff shall be provided on an equal basis by the Military Departments.

B. In exercising command of AFRRI, the Director, DNA, will be advised in matters of professional policy direction and related matters by a Board of Governors.

1. The AFRRI Board of Governors shall consist of the Director, DNA, as Chairman, and the Chief Surgeons General of the Army, Navy, and Air Force.

2. The Director, National Institutes of Health, and the Director, Division of Biology and Medicine, Atomic Energy Commission, or their designees, may be invited to participate in meetings of the Board of Governors when matters of mutual interest are being considered.

IV. FUNCTIONS

Under the direction, control and authority of the Director, DNA, and in accordance with appropriate DOD Directives and Instructions, AFRRI shall:

A. Operate facilities for conducting research on the biological effects of ionizing and disseminate the results.

B. Conduct advanced training in the field of biological effects of ionizing radiation to meet the internal requirement of the Institute, and those which may be developed and requested by other DOD Components.

C. Operate facilities for the production of short-lived radioisotopes for use in direct or collaborative research performed by the Institute.

D. Perform such other functions as may be assigned.

V. AUTHORITY

The appropriate provisions of reference (a) apply to the Director, DNA, in exercising command of AFRRI and fulfilling the functional responsibilities implicit in this Directve.

VI. ADMINISTRATION

A. The Military Departments will assign military personnel to AFRRI in accordance with approved authorizations. Procedures for such assignments will be as agreed upon between the Director, DNA, and the individual Military Departments.

B. Maintenance and operation of AFRRI normally will be programmed, budgeted and financed by DNA. This provision does not preclude AFRRI from participating in reimbursable activities subject to concurrence by Director, DNA.

C. The pay, allowances (including subsistence) and permanent change of station travel costs of military personnel assigned to AFRRI will be borne by the Military Department from which assigned.

VII. EFFECTIVE DATE AND CANCELLATION

This Directive is effective immediately. Reference (b) is hereby superseded and cancelled.

KENNETH RUSH,
Deputy Secretary of Defense.

applies to all years

These projects support the following goals:

1. Define and evaluate human response to nuclear weapon environments,
2. Define mechanisms of radiation injury,
3. Minimize or alleviate the deleterious effects of radiation by development of preventive or therapeutic measures, and
4. Correlate and apply biomedical research data to operational problems.

23. TECHNICAL OBJECTIVE.* 24. APPROACH, 25. PROGRESS (Furnish individual paragraphs identified by number. Precede text of each with Security Classification Code.)

OBJECTIVE: (U) To determine biological hazards associated with a long term exposure in an electromagnetic pulsed field. Data is required for evaluating potential occupational hazards associated with long term exposures to electromagnetic pulsed fields.

APPROACH: (U) Sixty male leukemia prone mice (AKA-J), 20 Mammary tumor prone female sprague-dawley rats and 150 male rats to be serially sacrificed for bioassay data will be exposed continuously (23 hr/day) in an EMP field for about a year. An equal number of animals will serve as controls. The exposure will consist of one pulse/second with a peake field intensity up to 500 KV/M with a mixed frequency component up to 100 MHZ. Data will be evaluated to determine if any abnormal biological effects such as an increased incidence and rate of neoplasms, changes in hamatological parameters, increased chromosomal aberrations, etc., occured during the exposure period.

PROGRESS: (U) JUL 73-JUN 75: Publications: Continuous exposure to rodents to 100 million pulses of electromagnetic radiation. AFRRI SR73-23, Health Physics 26:391-398, 1974: Biological effects on rodents exposed to pulsed electromagnetic radiation, AFRRI SR-73-10; Biological measurements in rodents exposed continuously throughout their adult life to pulsed electromagnetic radiation.' AFRRI SR75-11; Health Physics (1975) (in press).

(U) Microwave (U) Neurochemical Alterations (U). Neurotransmitters (U) Enzymes

23. TECHNICAL OBJECTIVE.* 24. APPROACH, 25. PROGRESS (Furnish individual paragraphs identified by number. Precede text of each with Security Classification Code.)

23.(U)Objectives: To determine the changes in levels of neurotransmitters and activities of enzymes involved in neurotransmitter metabolism in the central nervous system of microwave-irradiated animals.

24.(U)Approach: Studies performed mainly behind the Iron Curtain have indicated that microwave irradiation at low, non-thermal levels result in a number of neurological and behavioral effects in animals and humans. To substantiate Russian data, a systematic study will be conducted to determine if and to what extent neurochemical mechanisms in mammalian brain are affected by exposure of animals to low level microwave radiation. Groups of rats will be exposed to continuous low-level microwave radiation of 2450 MHz and approximately 10 mW/sq.cm. At various postirradiation time intervals levels of acetylcholine, norepinephrine, dopamine, and serotonin will be determined in discrete brain areas of experimental animals and sham-irradiated controls. Radiation-induced changes in activity of brain enzymes, choline acetyltransferase, acetylcholinesterase, tyrosine hydroxylase, cryptophan hydroxylase and monoamine oxidase which are involved in neurotransmitter metabolism, will also be determined. In a new series of experiments effect of microwave radiation on adenylcyclase-cyclic AMP and prostaglandin system will be determined. Micromethodologies currently in our laboratory will be used.

25.(U)Progress: None. (Ref. FY76 DH090142 MC91228).

23. TECHNICAL OBJECTIVE.* 24. APPROACH, 25. PROGRESS (Furnish individual paragraphs identified by number. Precede text of each with Security Classification Code.)

23.(U)Objectives:To determine (1)effect of microwave radiation on proteins in rabbit lens; (2)relationship between expected microwave-induced alterations of lenticular proteins and duration of exposure at constant power density.

24.(U)Approach:Test animals will be exposed to subcataractogenic and cataractogenic levels of 2.45 GHz radiation. Possible conversion of soluble lens proteins to an insoluble form during microwave-induced cataractogenesis will be investigated. Quantity of soluble protein will be determined after extraction of all soluble lens proteins in a suitable solvent. Variables in extraction procedure will be studied to determine if soluble protein is converted to insoluble protein by extraction procedure itself. After suitable extraction of lens proteins, quantity of alpha, beta, and gamma crystallins will be measured to determine possible alterations in protein concentration in rabbit lens as result of microwave insult. Each crystallin will be further analyzed to determine shifts in subunit composition and changes in chemical/physical properties attributable to microwave damage.

25.(U)Progress:1 Jul 75-1 Oct 76. Research to date has determined an appropriate microwave exposure regimen including exposure time and drug use. Evaluation of protein assay techniques such as pore-limit electrophoresis and SDS-electrophoresis are continuing. Experiments designed to determine appropriate pH, ionic strength and buffer composition are in progress. Experiments designed to evaluate effect of oxygen environment on lens proteins are on going. Equipment and techniques such as adsorption-elution from columns of DEAE cellulose and gel filtration, designed to fractionate lenses into classical components (alpha, beta, and gamma crystallins) are being readied for use in calibrating more sensitive electrophoretic assay systems. Animal irradiations are continuing. (Ref. FY77 DH 090224, MC 30309)

21. GENERAL USE

22. KEYWORDS (Precede EACH with Security Classification Code) (U)Serum Biochemistry; (U)Extremely Low Frequency Radiation; (U)Rats; (U)Weight Gain Effects

23. TECHNICAL OBJECTIVE,* 24. APPROACH, 25. PROGRESS (Furnish individual paragraphs identified by number. Precede text of each with Security Classification Code.)

23.(U)Objectives:(1)To determine the effect of extremely low frequency (ELF) electric field exposure on rats and study biological effects with emphasis on the mechanism of action. (2)To determine whether a relationship exists between ELF electric field-induced biological effects and the ELF electric field intensity.

24.(U)Approach:Rats will be exposed to a sinusoidal vertical electric field at 45 Hz initially, at 20 V/m (RMS). The environment, growth and health of the rats, and their food and water consumption will be monitored. At the termination of an irradiation period, serum samples will be taken. Serum analyses including total protein, globulin hematocrit, triglycerides, total free fatty acids, and cholesterol will be determined for each animal.

25.(U)Progress:1 Jul 75-1 Oct 76.An irradiator with six identical chambers to expose rats to vertical electric fields at ELF frequencies was constructed. Electric and magnetic fields associated with this irradiator have been characterized. A series of experiments at 45 Hz was completed. Analyses of rat growth rates, food and water consumption and key serum metabolite concentrations and hematology are nearing completion. Experiments to date using 48 control and 48 irradiated animals, suggest that exposure of rats to a vertical sinusoidal electric field strength of 20 V/m (RMS) produces no alteration in any growth, feeding, biochemical, hematological and pathological parameters measured. Fabrication of combined magnetic field, electric field, and ground return current simulation systems with MKS modulator at ELF frequencies is in progress. Report presented at USSI meeting, Boulder, Colorado, October 1975. Paper accepted for publication, Radio Science, 1976. (Ref FY77, DH 090225, MC 30310)

23. TECHNICAL OBJECTIVE,* 24. APPROACH, 25. PROGRESS (Furnish individual paragraphs identified by number. Precede text of each with Security Classification Code.)

23.(U)Objectives:To determine the changes in levels of neurotransmitters and activities of enzymes involved in neurotransmitter metabolism in the central nervous system of microwave-irradiated animals.

24.(U)Approach:Studies performed mainly behind the Iron Curtain have indicated that microwave irradiation at low, non-thermal levels result in a number of neurological and behavioral effects in animals and humans. To substantiate Russian data, a systematic study will be conducted to determine if and to what extent neurochemical mechanisms in mammalian brain are affected by exposure of animals to low-level microwave radiation. Groups of rats will be exposed to continuous low-level microwave radiation of 2450 MHz and approximately 10 mW/sq.cm. At various postirradiation time intervals levels of acetylcholine, norepinephrine, dopamine, and serotonin will be determined in discrete brain areas of experimental animals and sham-irradiated controls. Radiation-induced changes in activity of brain enzymes, choline acetyltransferase, acetylcholinesterase, tyrosine hydroxylase, cryptophan hydroxylase and monoamine oxidase which are involved in neurotransmitter metabolism, will also be determined. In a new series of experiments effect of microwave radiation on adenylcyclase-cyclic AMP and prostaglandin system will be determined. Micromethodologies currently in our laboratory will be used.

25.(U)Progress:Aug 75-Oct 76: An increased sensitivity to brain adenyl cyclase stimulation by PGE was observed. Preliminary measurements of thalamic-hypothalamic tryptophan hydroxylase activity and serotonin levels indicated marginal increases. One technical report has been published. (Ref. FY77 DH 090227, MC 30312)

DD FORM 1 MAR 68 1498

U.S. NUCLEAR REGULATORY COMMISSION,
Washington, D.C., June 24, 1977.

Hon. WARREN MAGNUSON,
Chairman, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: The NRC staff has prepared the attached response to your letter of May 26, 1977, requesting information on activities of the Nuclear Regulatory Commission in radiation research and regulation. The staff response describes the radiation-related research and regulatory programs conducted by the Nuclear Regulatory Commission pursuant to the Atomic Energy Act of 1954, as amended, and the Energy Reorganization Act of 1974, as amended. We trust that this information will be fully responsive to the questions which you posed. If we can be of further assistance, please do not hesitate to inform us of this.

Sincerely,

MARCUS A. ROWDEN,
Chairman.

NRC STAFF RESPONSE TO QUESTIONS BY SENATE COMMITTEE ON COMMERCE, SCIENCE, AND TRANSPORTATION, JUNE 1977

BACKGROUND

This paper was prepared by the staff of the Nuclear Regulatory Commission. It responds to an inquiry of May 26, 1977, by Senator Warren Magnuson, Chairman of the Senate Committee on Commerce, Science, and Transportation. The inquiry was in connection with hearings planned by the Committee to review and evaluate Federal radiation research and regulatory programs. The Committee keyed its questions to the period from 1968 to 1977, the years since the enactment of the Radiation Control for Health and Safety Act of 1968 (PL 90-602).

Senator Magnuson's letter requested a tabular matrix of resources to show agency expenditures over the period of interest, and also posed four specific questions concerning NRC jurisdiction, Federal/State coordination, and proposals for improvement of radiation protection programs. Responses to these questions appear in subsequent sections of this staff paper, following a summary of the role of the Nuclear Regulatory Commission in relationship to other Federal and State agencies having radiation protection and public health responsibilities.

ROLE OF NRC

The statutory authorities of the NRC derive from the Atomic Energy Act of 1954, as amended, the Energy Reorganization Act of 1974, as amended, and the National Environmental Policy Act of 1969. The basic authorities from the Atomic Energy Act include licensing and regulation of production, use, possession, ownership of special nuclear materials, source material, and byproduct materials, and licensing and control over the manufacture, production, possession, use, importation or exportation of production and utilization facilities.

The term "special nuclear material", as used in the Act and in NRC regulations, covers plutonium, uranium enriched in the isotopes U-233 or U-235, any material artificially enriched in these materials, and other materials as specified by the NRC. The term "source material" generally means uranium (not enriched) or thorium and may apply to other materials as specified by the NRC. The term "byproduct materials" includes any radioactive material (except special nuclear material) produced in or made radioactive by exposure to the radiation incident to the process of producing or utilizing a special nuclear material. For practical purposes, this means any radionuclide produced in a nuclear reactor or by irradiation by special nuclear material. The definition generally excludes certain naturally occurring radioactive materials (except those otherwise defined as source materials) and accelerator produced radioisotopes.

A production facility is any equipment or device or part thereof (as determined by the Commission) capable of producing special nuclear material in such quantity as to be significant to the common defense and security. A utilization facility is a device or part thereof (except an atomic weapon) which employs special nuclear materials in such quantities or in a manner to affect the health and safety of the public or be of significance to common defense or security. As examples of these terms, a nuclear power reactor is classified as a utilization facility and a spent fuel processing plant is considered a production facility.

The regulation of these activities in order to protect public health and safety is achieved through: (1) the formulation of rules and regulations; (2) the implementation of these rules and regulations in individual licensing actions which set forth specific requirements for each licensee; (3) a hearing process for permitting public participation in case-by-case licensing actions; (4) an inspection and enforcement program to insure compliance with the regulations and license conditions, and (5) a confirmatory research program to develop the information required to support the licensing and other regulatory functions.

These activities are coordinated with other Federal and State agencies as explained in detail below. For example, the Environmental Protection Agency (EPA) has a lead role in establishing generally applicable standards for radioactivity in the environment and Federal guidance on radiation protection. The NRC implements standards and guidance of these types developed by EPA. The Commission places particular emphasis on coordinating development of environmental radiation standards with EPA. The Commission also coordinates very closely with ERDA on research activities involving radiation protection and the engineering sciences which are important to the safety of activities regulated by NRC.

The NRC regulatory program for protecting public health and safety from exposures to radiation resulting from routine operations and from releases of radioactive materials to the environment is based on consideration of the need to assure adequate protection to the public health and safety and upon a weighing of societal costs and benefits. The basic objectives of the NRC program for protection against radiation can be summarized as follows:

(*a*) To keep radiation doses from all sources of exposure, other than natural background and medical procedures, below the numerical limits of the radiation protection guides.

(*b*) To avoid unnecessary sources of exposure and to ensure that doses received are justifiable in terms of benefits that would not otherwise have been received.

(*c*) To provide for design and operational control of specific facilities and uses of materials, both individually and in combination, so that the resulting doses are sufficiently low that any further reduction in risk would not be considered to justify the effort required to accomplish it; that is, the doses are "as low as reasonably achievable."

In addition, there is a recent trend to include another basic consideration in the regulatory decision process for radiation protection. That is, the trend to make comparisons of radiation criteria and risks with the criteria and risks associated with non-nuclear environmental pollutants or occupational hazards. This has led to the utilization of new and evolving methods for risk and cost-benefit analysis so that public health and worker protection decisions for a myriad of activities can eventually begin to be made after considering comparability of societal risk and allocation of national resources, in addition to the best available scientific information on health and safety effects.

As a result, the NRC program for regulation of radiation includes consideration of many factors, such as: balancing of societal interests, technical feasibility, cost-benefit analysis, value analysis, alternative actions, quantification of potential health effects, probabilities and ranges of uncertainty for exposures and for over-all-risk evaluations for individuals and for population groups. These factors, which in past years were only considered qualitatively (if at all), are responsive to the evolutionary trend of public health protection toward a contemporary philosophy eliminating unnecessary hazards and keeping levels of exposure and risks "as low as reasonably achievable."

RESOURCES FOR RADIATION RESEARCH AND REGULATORY PROGRAMS

Most of the Nuclear Regulatory Commission's resources are dedicated to assuring that there will be no undue risks to the health and safety of the public from licensed nuclear activities. Taking this broad view that substantially all NRC efforts are related directly or indirectly to radiation programs, that is, the purpose of the regulatory program is to reduce or to prevent exposures to radiation in routine operations and in potential accident or sabotage situations, then the NRC manpower and other resources spent on "radiation research and regulatory programs," the terms used by the Committee, would be close to correspond to the total NRC budget. The total budgets for the years since NRC was formed in 1975, to date, are:

1975:	
Persons	2, 006
Amount (millions)	$148
1976:	
Persons	2, 289
Amount (millions)	$222
1977:	
Persons	2, 529
Amount (millions)	$256
1978:	
Persons	2, 695
Amount (millions)	$292

These annual budget totals are subdivided in Table 1 according to NRC functional activities.

However, some of the NRC effort is in consideration of nonradiological environmental issues, such as socioeconomic impacts and chemical and thermal discharges, or anti-trust considerations. We have attempted to subtract resources used in such efforts and to use the format suggested by the Committee in their correspondence to us. Table 2 presents resource expenditures adjusted in such a manner for the principally involved offices of NRC, namely Nuclear Reactor Regulation, Nuclear Materials Safety and Safeguards, Nuclear Regulatory Research, Inspection and Enforcement, State Programs and Standards Development.

TABLE 1.—NRC ANNUAL BUDGET AND AUTHORIZED MANPOWER, 1975–78

[Dollar amounts in millions]

	1975		1976		1977		1978	
	Persons	Amount	Persons	Amount	Persons	Amount	Persons	Amount

$\$M^1$= Total NRC resources spent in millions of dollars

Question 1. What changes in your jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Response. On January 19, 1975, the U.S. Nuclear Regulatory Commission, established pursuant to section 201 of the Energy Reorganization Act of 1974, as amended,[1] assumed the licensing and related regulatory functions vested in the former U.S. Atomic Energy Commission by the provisions of the Atomic Energy Act of 1954, as amended.[2] A major objective of the Energy Reorganization Act of 1974, which became law October 11, 1974 and went into effect January 19, 1975, was to separate the developmental and promotional responsibilities of the Atomic Energy Commission from its licensing and related regulatory functions. The Act abolished the Atomic Energy Commission and established two new agencies in its place—the Energy Research and Development Administration, a new independent executive agency, and the Nuclear Regulatory Commission, a new independent regulatory commission. In addition to assuming the licensing and related regulatory responsibilities of the former AEC, the NRC was also given express authority to license and regulate certain ERDA activities.[3]

The regulatory jurisdiction of the NRC is basically the same as that of the former Atomic Energy Commission which has remained substantially unchanged since 1954.[4] Thus, the statutory mission of the Nuclear Regulatory Commission is to regulate civilian nuclear energy activities to ensure that they are conducted in a manner which will protect the public from the standpoint of radiological health and safety, maintain national security and comply with the antitrust laws. (Following the enactment of the National Environmental Policy Act of 1969, the Commission was charged with the responsibility of carrying out these functions in a manner which will protect the environment). To this end, the Commission is empowered to license and regulate utilization and production facilities (e.g., nuclear power plants and fuel reprocessing plants), source material (e.g., uranium and thorium), byproduct material (e.g., radioisotopes), and special nuclear material (e.g., plutonium and enriched uranium), and certain activities of the Energy Research and Development Administration. The Commission's regulatory authority does not extend to naturally occurring radioactive materials (other than source materials) such as radium or to accelerator-produced radioactive materials.

Although the Commission's jurisdiction has remained substantially the same, except for the transfer to EPA under Reorganization Plan No. 3 of 1970 of certain functions of the former Atomic Energy Commission respecting the establishment of "generally applicable environmental standards for the protection of the general environment from radioactive material," [5] amendments to the Atomic Energy Act, both prior to 1968 and during the period 1968–1977 and the enactment of new laws, principally laws designed to protect the environment, have changed the manner in which the Commission has exercised its basic authority and the matters which it must consider in carrying out its regulatory responsibilities.

Two examples of amendments to the Atomic Energy Act which have altered the Commission's responsibilities are: Public Law 91–161, December 24, 1969, 83 Stat. 444, which added a new section 234 to the Atomic Energy Act of 1954, as amended, authorizing The Commission, in addition to, or in lieu of, taking administrative action such as suspending or revoking a license or issuing a cease and desist order, to impose civil monetary penalties on persons who violate the licensing provisions of the Act or any rule, regulation, order or license issued thereunder. This added authority was designed to give the Commission more flexibility in dealing with infractions of varying severity.

---

[1] Pub. Law 93–438, 88 Stat. 1233 at 1242, as amended by Pub. Law 94–79, 89 Stat. 413–414 (42 U.S.C. 5841), Executive Order 11834, dated January 15, 1975, 40 FR 2871, January 17, 1975.

[2] Pub. Law 83–703, as amended, 68 Stat. 919 (42 U.S.C. Ch. 23).

[3] Sec. 202, Energy Reorganization Act of 1974, 88 Stat. 1244, 42 U.S.C.A. § 5842.

[4] The Atomic Energy Act of 1954, which amended the earlier Atomic Energy Act of 1946, was enacted to provide a legal framework within which government and industry could work together to develop and promote and the government would regulate the industrial and commercial uses of atomic energy for peaceful purposes. These uses included the construction and operation of nuclear power plants and the use of byproduct material and special nuclear material in various forms and devices for industrial and medical purposes.

[5] Reorganization Plan No. 3 of 1970, effective Dec. 2, 1970, 35 FR 15623, 84 Stat. 2086, 5 U.S.C.A. Appendix II Reorganization Plans, 1977 Cumulative Annual Pocket Part. See Attachment A, pp. 6–9 for a detailed discussion of this transfer.

Public Law 91–560, December 19, 1970, 84 Stat. 1472, which amended the Atomic Energy Act of 1954, as amended, to eliminate the requirement for finding of "practical value" by the AEC before nuclear facilities (such as power reactors and fuel reprocessing plants) can be licensed under the "commercial section" (section 103) of the Act. The principal effect of this change was to subject applications for section 103 facility licenses to pre-licensing antitrust review by the Attorney General and the Commission. Consistent with this change, Public Law 91–560 amended the provisions of section 191a of the Act which prescribe the qualifications of members of Atomic Safety and Licensing Boards to permit the Commission to appoint as Board members persons with expertise appropriate to the issues to be decided. In addition, the general notice provision (section 182c) was amended to assure that various regulatory agencies and others received adequate notice of the application.

In addition, the Commission's exercise of its authority has also been affected by the 1975 amendment of section 201 of the Energy Reorganization Act of 1974.

In 1975, Congress amended section 201 of the Energy Reorganization Act of 1974 (Public Law 94–79, August 9, 1975, 89 Stat. 413–414) which, in addition to providing that the Chairman of the Commission shall serve as its principal executive officer and clarifying certain provisions relating to the terms of the Commissioners, also included the following provision:

"The Nuclear Regulatory Commission shall not license any shipments by air transport of plutonium in any form whether exports, imports or domestic shipments: *Provided, however*, That any plutonium in any form contained in a medical device designed for individual human application is not subject to this restriction. This restriction shall be in force until the Nuclear Regulatory Commission has certified to the Joint Committee on Atomic Energy of the Congress that a safe container has been developed and tested which will not rupture under crash and blast-testing equivalent to the crash and explosion of a high-flying aircraft."

On August 15, 1975, the Commission's Office of Nuclear Material Safety and Safeguards issued an order stopping the shipment of plutonium by air. Since that time the Commission has been engaged in developing a safe container which can be certified to the Joint Committee as meeting the statutory requirements. Attachment A contains a detailed discussion of the way in which the Commission's jurisdictional responsibilities have been affected during the period from 1968–1977 by the National Environmental Policy Act of 1969 and by authority exercised by other Federal agencies in the areas of environmental protection, transportation, nuclear medicine and in connection with the regulation of floating nuclear power plants and nuclear power electric generating stations located on coastal and inland navigable waters. The authorities vested in the Secretary of the Department of Health, Education, and Welfare under the Radiation Control for Health and Safety Act of 1968, which is concerned with radiation caused by the operation of an electronic circuit, have not impinged on the Commission's licensing and related regulatory function.[6]

As indicated above and as described more fully in Attachment A, the Nuclear Regulatory Commission has accommodated changes in jurisdiction and the impacts of other laws on its regulatory authority in a number of ways, including negotiation and execution of formal Memoranda of Understanding, participation on interagency committees and in the interagency comment process, changes in NRC regulations and licenses, and use of informal cooperative procedures.

Question 2. Would you please describe the nature of the contacts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with State agencies? Is there any confusion concerning respective responsibilities of State and Federal agencies?

Response. The Commission recognizes that the States have a growing interest in the work of our agency and are playing an increasingly important role in our regulatory process. In July 1976, the Commission established a separate Office of State Programs (OSP) with responsibility for improving and enhancing our relations with the States. The OSP is charged with certain aspects of our agency's emergency preparedness efforts, the supervision of the Agreement States program and certain of the other programs mentioned below.

---

[6] Section 4 of the Radiation Control for Health and Safety Act states that "The amendments made by section 2 of this Act shall not be construed as superseding or limiting the functions, under any other provision of law, of any officer or agency of the United States."

In addition, under section 274 of the Atomic Energy Act, the Commission is authorized to enter into agreements with States by which they assume regulatory responsibility for certain kinds, quantities, and uses of radioactive materials. Twenty-five Agreement States now administer over 55% of the effective licenses in the United States. The Commission is currently reexamining this program with a view to assuring effective Federal standards and broad State participation, as well as possibly increased areas of State responsibility. The Commission expects to have the results of this study available within the next few weeks.

On March 24, 1977, the Chairman of NRC wrote to each State Governor and requested their candid and direct views on whether the present arrangement under the Atomic Energy Act of 1954, as amended, of exclusive Federal control over radiation health and safety requires revision and, if so, what form should changes take. Of the twenty responses received to date, fourteen Governors said that no changes in the current regulatory scheme were necessary. Reasons cited for continuing Federal control are the complex nature of the facilities and the financial burden of establishing a competent technical review organization at the State level.

Two Governors (Oregon and Arkansas) indicated that the Federal government should act as a coordinator of State activities, set standards and establish an Agreement State concept for monitoring and enforcement authority around nuclear facilities. The Governors of Connecticut and Michigan indicated that the States needed to play a more meaningful role and that Federal and State agencies should share decisions. The Governor of Kentucky supports the view that the Federal government should own low-level burial facilities and they should be regulated jointly by the State and Federal governments. Additionally, he suggests that Federal regulation be extended to include the use of radioactive materials which are not presently covered by the Atomic Energy Act.

A number of Governors state strong support for the continuation of the Agreement State Program whereby the Commission relinquishes regulatory authority over source, byproduct and small quantities of special nuclear materials to the States.

General opinion favors early notification to a State and neighboring States of the possible location of a nuclear facility within a State. All information concerning application for license made to NRC should be made available to the State with sufficient opportunity for State discussions with the NRC and with the applicant.

No State indicated the necessity for a State to decide on the radiological safety of a particular facility. The general consensus apparently is that the States want to be involved in the process to assure themselves and their citizens that the Federal performance meets the needs of the States.

Of particular interest to the Governors was the States' role in planning for energy development. Nine Governors indicated that States should make the decisions on siting need for power, land use, and the social and physical environment. South Dakota suggested that a State's "need for power" determination should be binding on the Federal Government.

One Governor (Montana) recommended that the Atomic Energy Act be amended to allow States to impose more stringent radiological effluent standards than those established by the Federal Government.

These suggestions are being addressed in ongoing staff studies at NRC.

The Commission has also directed its staff to study means to increase effectiveness in the siting of nuclear facilities. The study has now been released by the Commission as a preliminary staff statement. The statement is titled: "Improving Regulatory Effectiveness in Federal/State Siting Actions", May 1977, Report No. NUREG 0195. The statement makes five important recommendations aimed at improving the coordination of Federal reviews.

1. That Federal legislation authorize coordinated early and open planning by utilities and States or associations of States for all forms of electrical generation.
2. That the National Environmental Policy Act of 1969 be amended to allow Federal agencies to accept for inclusion in final environmental impact statements environmental reviews performed by qualified States acting under carefully constructed Federal guidelines.
3. That States be authorized to certify sites for generating facilities.
4. That State certification of need for power (facility) be final and binding on Federal agencies.

5. That coordination of Federal and State regulatory actions be emphasized in order to minimize duplication and create a commonly available data base.

Attachment B[1] is a copy of the Executive Summary from NUREG 0195.

On a related matter, the Commission has increased its emphasis on the conduct of joint hearings with States with respect to matters to concurrent jurisdiction. First initiated in Maryland, his process is now underway in New York State, and, recently, Massachusetts has requested joint hearing on a pending license. The Commission hopes to make this approach widely known to the States. In a similar way, the Commission has been encouraging the development of understandings with States to promote more efficient discharge of mutual responsibilities.

Several other items are worthy of note: the Commission provides training to State and local officials in radiological health and safety matters, as well as in preparedness for radiation emergencies. It also provides assistance and technical support to States in responding to radiological incidents. As a matter of routine, NRC regional offices promptly notify the States of significant or unusual events involving NRC-licensed facilities or activities within their borders. The Commission supports through contracts the Conference of (State) Radiation Control Program Directors, and NRC has a number of cooperative arrangements with States where reactors are located for environmental radiation monitoring and also has data collection contractual agreements in some of the States. Also, in conjunction with the Department of Transportation, the Commission has developed a three-year cost sharing program to help States monitor the transport of low-level radioactive material within their borders. Since 1975, the Commission has been working with State geology agencies to develop regional seismotectonic maps, an important aspect of future plans to standardize the Commission's approach to seismic risk assessment in the Eastern United States.

The Commission has also encouraged the States to appoint liaison officers to deal with the Commission on a day-to-day basis, particularly in the area of our non-radiological environmental review process. To date, twenty-four Governors have made such appointments. The Commission has also instituted a long-range study on the feasibility of assigning various Commission functions to our regional offices and. as a first step, the Commission decided on a pilot program to place State liaison officers in some or all of NRC's five regional offices.

We have a continuing joint activity we are engaged in with the Bureau of Radiological Health and the Conference of Radiation Control Program Director for the development and updating of suggested State Regulations which provide a framework for the control of radioctive materials and also radiation producing machines. A number of States, both NRC Agreement States and some non-Agreement States, make use of these suggested regulations.

In response to requests from the Conference of Radiation Control Program Directors and from the Agreement States, the NRC formed a Task Force to review the matter of regulation of naturally occurring and accelerator produced radioactive materials. Such radioactive materials are not now subject to NRC licensing and regulation. The Task Force's work is nearing completion and a report expected to be available in the near future.

Recently, the NRC published effective rules establishing procedures for early site review of proposed nuclear reactor power stations (42 FR No. 87, 22882–22888 May 5, 1977, effective June 6, 1977). Some States originally had expressed concern that State regulatory processes would be adversely affected. In response to these concerns, the Commission made substantial changes in the effective regulation to encourage State and local government participation in early site review proceedings. It is the Commission's intent to consider carefully the needs and desires of State and local officials in the actions taken under the early site review rule.

Some of the NRC/State power plant site evalution efforts address regional issues. In one such effort currently underway in the Southeastern States a long-range utility energy facility siting project is being studied as a possible regional siting demonstration project, and mechanisms are in place to ensure early public involvement along with coordinated Federal, regional, and State site reviews.

Question 3. Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved? Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

---

[1] Attachment B is in the committee files.

Response. Regulation of activities pursuant to the Atomic Energy Act is, appropriately, the responsibility of the NRC, in some areas delegated to the 25 Agreement States. In the past, there has been some uncertainty regarding the authorities and responsiblities of EPA and NRC in establishing the radiation standards within which this regulation occurs. Occasionally this has led to confusion which has the potential for duplication of efforts or for contradictory requirements.

In developing sound and workable standards, the NRC must work effectively with many groups, both within and outside Government. In this regard, the Commission places particular emphasis on coordinating the development of environment standards, particularly radiation standards, with the Environmental Protection Agency and other concerned parties.

The funding levels for the regulation of radiation programs and research conducted by NRC pursuant to the Atomic Energy Act and the Energy Reorganization Act and approved by Congress on a yearly basis are adequate.

Question 4. What is your reaction to the proposals to consolidate all Federal radiation activities into one Federal radiation agency?

Response. The term "radiation activities" covers Federal programs now divided among several agencies. For example, the Food and Drug Administration, because of its particular expertise in the medical applications of X-rays, regulates X-ray devices; the Environmental Protection Agency sets standards of general applicability pertaining to radiation; and NRC regulates radiation health and safety issues pertaining to activities, facilities, and materials under the Atomic Energy Act of 1954 and the Energy Reorganization Act.

We believe that some consolidation of Federal radiation activities could result in a reduction of duplication, particularly in the area of the authorities and responsibilities of EPA and NRC, as we mentioned in our response to question 3. The greatest potential overlap is with EPA's standards-setting activities, where the need for coordination is appreciated by both agencies and was treated explicitly in Reorganization Plan No. 3 of 1970. Other limited aspects of NRC jurisdiction have from time to time been duplicated in other agencies, both Federal and State, but the Supreme Court has recently reaffirmed NRC's preemptive regulatory authority under the Atomic Energy Act over radiological health and safety aspects of nuclear generating facilities. *Train* v. *Colorado Public Interest Research Group*, 426 U.S. 1 (1976).

The Environmental Protection Agency, in exercise of the authority of the Federal Radiation Council, can assure uniformity of approach and balance in the field of radiation protection. Under this authority EPA can develop Federal radiation guidance for promulgation by the President. We understand that development work of this sort is being contemplated or is already underway in several areas.

Consideration of the question of adjustments of authority within the Federal government could also appropriately consider the important related issue of adjustments in regulatory authority between the Federal government and the States. Some of these issues will be discussed in the forthcoming "Task Force Report on Naturally Occurring and Accelerator Produced Radioactive Materials" referred to in our response to question No. 2, above.

It is essential, of course, that any reorganization be carefully structured so as to assure that in the interests of greater efficiency, changes are not made which result in a diminution of protection to the public in these extremely important areas. It must be recognized that the diversity of the sources and uses of radiation—from microwave ovens in the home to nuclear powerplants—requires varying regulatory treatment, whether regulation is assigned to one agency or several.

NRC would appreciate the opportunity to address the merits of any consolidation which may be proposed.

ATTACHMENT A

EXERCISE OF NRC JURISDICTION

I. ENVIRONMENTAL PROTECTION

A. NEPA-RELATED STATUTORY AUTHORITIES

Pursuant to the provisions of the National Environmental Policy Act of 1969 (NEPA), the Nuclear Regulatory Commission is required to carry out its licensing and related regulatory responsibilities in a manner which will protect and enhance the environment. Specifically, the Commission is required, in accordance with the environmental impact statement procedures prescribed by section 102(2)(C) of NEPA (42 U.S.C. 4332), to evaluate the environmental impacts of each proposed major action and the available alternative actions and, to determine, on the basis of an analysis which considers and balances the environmental effects of the facility, the alternatives available for reducing or avoiding adverse environmental effects, and economic, technical and other costs and benefits, whether a license or permit for a nuclear power plant or other facility or activity should be issued, denied or issued with conditions designed to mitigate undesirable environmental effects.

In carrying out its responsibilities under NEPA, the Commission has become aware of certain areas in which its responsibilities impinge on those of other Federal agencies. In these areas of common concern, the broad environmental review responsibilities vested in NRC by NEPA overlap with other more specific environmental review responsibilities related to nuclear activities vested in other Federal agencies—e.g., The Federal Water Pollution Control Act, as amended, Coastal Zone Management Act of 1972, Wild and Scenic Rivers Act, National Historic Preservation Act, Endangered Species Conservation Act, Fish and Wildlife Coordination Act. At present, these overlaps are most substantial in connection with implementation of the Federal Water Pollution Control Act Amendments of 1972. These overlaps could be substantial in connection with the implementation of the Coastal Zone Management Act.

1. The Federal Water Pollution Control Act Amendments of 1972 (hereafter referred to as FWPCA), Public Law 92–500, October 18, 1972, 86 Stat. 816 et seq.

Background.—Prior to the enactment of the National Environmental Policy Act of 1969 (NEPA), Federal and State agencies other than the Atomic Energy Commission (NRC's predecessor) exercised control over the discharge of nonradiological pollutants, such as heat, from nuclear power plants. Following the enactment of NEPA and the Water Quality Improvement Act of 1970, but prior to the enactment of the 1972 amendments to the Federal Water Pollution Control Act, AEC was precluded from issuing construction permits for nuclear power plants until a water quality certificate from the state in which the proposed facility was to be located was furnished (33 U.S.C. 1171(b)). This certificate, known as a "21(b) certificate" after the section of the Federal Water Pollution Control Act which established the need for it, had to indicate that there was "reasonable assurance" that the discharges from the facility would not violate the State's water quality standards. In addition to insuring that such a certificate was obtained, AEC understood its obligations under NEPA to require that it make an independent appraisal of the impact of the discharge on water quality, implement any cooling system alternatives that could, at a favorable cost-benefit balance, reduce the impact of the discharge, and consider any residual adverse environmental impact in the overall cost-benefit balance.

The Federal Water Pollution Control Act Amendments of 1972 expanded the role of the Environmental Protection Agency with respect to the protection of water quality. At the same time, in furtherance of a policy of reducing "needless duplication and unnecessary delays at all levels of government"[1] it significantly reduced the scope of the obligations otherwise assigned to the Commission under NEPA (sec. 511(c)(2), FWPCA, 33 U.S.C. 1371(c)(2)).

Pursuant to section 402 of the FWPCA (33 U.S.C. 1342), EPA is authorized to issue a permit allowing the discharge of a pollutant if the discharge complies with certain standards established by the provisions of the FWPCA. (See e.g., secs. 301, 302, 306, 307, 308, 316, 403, 33 U.S.C. 1311, 1312, 1316, 1317, 1318, 1326, 1343.) Heat and chemical wastes are discharged from nuclear power plants and are considered pollutants within the meaning of the FWPCA (33 U.S.C. 1362(b)). However, pursuant to the opinion of the U.S. Supreme Court in *Train* v. *Colorado Public Interest Research Group, Inc.*, 426 U.S. 1, June 1, 1976, source, byproduct and special nuclear materials regulated by NRC are not pollutants within the meaning of the FWPCA.

The Federal Water Pollution Control Act Amendments of 1972 changed the role of the former Atomic Energy Commission (now exercised by the Nuclear Regulatory Commission) in this regulatory scheme. Instead of the prior requirement that NRC obtain a state certification of reasonable assurance that state water quality standards will be met, NRC is now required to obtain a state certification (sec. 401, FWPCA, 33 U.S.C. 1341) that the proposed discharge will comply with Federal standards, i.e., with certain applicable provisions, such as section 301, of FWPCA. Certain requirements and limitations contained in this certificate must be included as conditions in the NRC permit or license. If the requisite certificate is denied, NRC is prohibited by section 401, as it was also prohibited by sec. 21(b), from issuing a permit or license. Section 511 of the FWPCA (33 U.S.C. 1371) explicitly provides that nothing under NEPA shall be deemed to authorize any Federal agency to review any effluent limitation or other requirement established pursuant to the FWPCA, or to impose, as a condition of any license or permit, any effluent limitation other than any such limitation established pursuant to the FWPCA.

---

[1] Sec. 101(f), FWPCA, 33 U.S.C. 1251(f).

These statutory changes have altered the nature of NRC's NEPA review. Instead of specifying requirements for inclusion in permits and licenses to minimize aquatic environmental impacts from nuclear power reactors, NRC's role is confined to evaluating, as one factor in the overall cost-benefit balance prescribed by NEPA, the environmental impacts of nuclear facilities on water quality assuming EPA standards and requirements have been met. Thus, both NRC and EPA (or permitting States under sec. 402 of the FWPCA, 33 U.S.C. 1342) must evaluate water pollution impacts, but EPA and the States have the preeminent role in setting and enforcing water pollution standards and limitations.

For the system to work to maximum advantage, it is necessary for EPA to have made its determination relative to a nuclear power plant's cooling system in advance of NRC's consideration of the matter. The close interface between the respective statutory authority of EPA and NRC in the area of water quality and the resultant problems of implementation led NRC and EPA on December 17, 1975 to enter into a Second Memorandum of Understanding to clarify their respective roles in the decision-making process concerning nuclear power plants and other facilities requiring an NRC license or permit. A copy of this Second Memorandum of Understanding, which became effective January 30, 1976, is attached. (Second Memorandum of Understanding is available in committee files.)

The purpose of the Second Memorandum of Understanding is to reduce demands for water quality data placed on applicants for nuclear facilities by assuring that applicants' environmental reports contain sufficient information to meet both NRC's needs under NEPA and EPA's needs under the FWPCA, and to minimize any duplication of effort between NRC and EPA in meeting their respective responsibilities under NEPA and the FWPCA.

The Second Memorandum of Understanding provides, among other things, that:

> NRC is to serve as the lead agency for preparation of environmental impact statements for nuclear facilities;
>
> NRC and EPA will cooperate in identifying and consolidating their respective requirements under NEPA and FWPCA for water quality data;
>
> EPA will participate with NRC in the evaluation of water quality impacts;
>
> In those states which do not have NPDES permitting authority, EPA will issue NPDES section 402 permits, section 316(a) exemptions and section 316(b) analyses of intake structures "as far as possible in advance" of the date of issuance by NRC of its final environmental impact statement; (Emphasis supplied.)
>
> NRC and EPA will consider the feasibility of holding joint or concurrent hearings.

Circumstances in which EPA's FWPCA responsibilities and NRC's NEPA responsibilities are most likely to cause difficulties are those in which EPA's FWPCA requirements with respect to a particular nuclear facility (the need for cooling towers or the location of water intake structures, for example) have not been finally determined. In those instances in which a proposed applicant is seeking a section 316(a) exemption from EPA, any uncertainty as to the final disposition of the applicant's request before EPA can have a significant impact on both the scope and outcome of NRC's NEPA review, since it is possible that in some cases NRC may be unable to complete its NEPA review without knowledge of the requirements to be imposed under FWPCA. In at least one case, uncertainty as to final action on a section 402 discharge permit has had a substantial impact on the Commission's licensing process.

2. *Coastal Zone Management Act of 1972 as amended, Pub. Law 92–583, October 27, 1972, 86 Stat. 1280, 16 U.S.C.A. §§ 1451, et seq.*

The Coastal Zone Management Act of 1972, as amended, establishes a statutory scheme, under which states are encouraged, with Federal assistance, to develop and implement coastal zone management programs which will achieve wise use of the land and water resources of the coastal zone giving full consideration to ecological, cultural, historic, and esthetic values as well as the need for economic development. State coastal zone management programs are required to include a "planning process for energy facilities likely to be located in, or which may significantly affect, the coastal zone, including but not limited to, a process for anticipating and managing the impacts from such facilities." The term "energy facilities", as defined in the Act, includes electric generating plants (nuclear power reactors fall in this category) and uranium enrichment and nuclear fuel processing facilities. These facilities are subject to regulation by NRC.

In passing the Coastal Zone Management Act, Congress included a provision (usually referred to as the "FEDERAL CONSISTENCY" provision, Section 307, as amended, 16 U.S.C.A. § 1456) to encourage states to enter into the program and to promote comprehensive Federal-State cooperative coastal zone land and water use management. Generally, the provision requires Federal agencies to administer their direct activities, regulatory functions, and assistance programs in a manner consistent with approved state coastal management programs. Pursuant to subsection (c)(3)(A) of section 307 (16 U.S.C.A. 1456(c)(3)(A)), any applicant for a required Federal license or permit to conduct an activity affecting land or water uses in the coastal zone of a state with an approved coastal zone management program shall provide in his application for a federal permit or license ". . . a certification that the proposed activity complies with the state's approved program and that such activity will be conducted in a manner consistent with the program. . . ."

This subsection also provides that: "No license or permit shall be granted by the Federal agency until the state or its designated agency has concurred with the applicant's certification or until, by the state's failure to act, the concurrence is conclusively presumed, unless the Secretary, on his own initiative or upon appeal by the applicant, finds, after providing a reasonable opportunity for detailed comments from the Federal agency involved and from the state, that the activity is consistent with the objectives of this chapter or is otherwise necessary in the interest of national security."

The national coastal zone management program has now reached the stage where a number of states are completing development of their management programs and will be seeking the requisite approval of those programs which must be obtained in order to trigger the requirements of the Federal Consistency provision. The Department of Commerce is currently engaged in developing proposed regulations to be issued for public comment to implement that provision.

Although it is still too early to evaluate the workability of the Federal Consistency provision and its impact on NRC's regulatory program, indications are that the certification and state concurrence requirements of section 307(c)(3)(A) could become an important factor in NRC's grant of construction permits and licenses for facilities which are either located in coastal zones or are located in areas outside of but affecting coastal zones. Under NEPA, NRC would be required to independently evaluate coastal zone impacts, notwithstanding the approval of the proposed license by the State and/or Secretary.

B. RADIOLOGICAL-RELATED STATUTORY AUTHORITIES

1. *Authority transferred to EPA by Reorganization Plan No. 3 of 1970 to carry out*

(a) Certain functions of the former Atomic Energy Commisison respecting the establishment of "generally applicable environmental standards for the protection of the general environment from radioactive material."

(b) All functions of the Federal Radiation Council.

(*a*) *Transferred functions relating to generally applicable environmental radiation standards*

The functions transferred from the former AEC respecting the establishment of generally applicable environmental standards were those administered by the AEC's Division of Radiation Protection Standards. These standard-setting functions involved the establishment of ambient standards, i.e., limits on radiation exposures or levels, or concentrations or quantities of radioactive material, in the general environment outside the boundaries of locations under the control of persons possessing or using radioactive material.

In the message to Congress transmitting Reorganization Plan No. 3 of 1970, the President stated that "AEC would retain responsibility for the implementation and enforcement of radiation standards through its licensing authority."

Recognizing their complementary responsibilities in the areas of environmental protection and the control of radiation effects occasioned by this transfer of functions, EPA and the former AEC executed a Memorandum of Understanding with respect to AEC-Licensed Facilities in August 1973. The purpose of this Memorandum of Understanding (copy attached)[1] was "to fix an appropriate interface of the respective functions of the two agencies, to further facilitate their useful cooperation, and to avoid unnecessary duplication of regulatory effort, . . ."

On January 13, 1977, pursuant to its transferred authority to set generally applicable environmental standards, EPA published a new Part 190 to its regulations (40 CFR Part 190—Environmental Radiation Protection Standards for Nuclear Power Operations; 42 FR 2858–2861) establishing environmental radiation protection standards for the uranium fuel cycle. These standards specify levels below which normal operations of the uranium fuel cycle are determined to be environmentally acceptable.

In the statement of considerations which accompanied the rule, EPA stated that "[t]he authority to regulate fuel cycle facilities under these standards resides in the Nuclear Regulatory Commission . . ." EPA also pointed out that "[i]n situations where members of the public are actually exposed, these standards, [40 CFR Part 190] in effect, preempt those regulations which are based upon the Federal Radiation Protection Guides (25 FR 4402) insofar as exposure of the public is due to operations defined to be included in the uranium fuel cycle. For example, the dose limits in 10 CFR Part 20 [NRC regulations establishing standards for protection against radiation hazards arising out of activities under licenses issued by NRC] would not be the limiting consideration regarding exposure of members of the public as a result of uranium fuel cycle operations. . . ."

As contemplated by the provisions of the 1973 Memorandum of Understanding, NRC staff has recently established a task group to prepare recommendations for Commission consideration on the regulatory changes which will be needed to implement EPA's Uranium Fuel Cycle Standard. In theory, there will be no conflict between NRC's and EPA's responsibilities under the Atomic Energy Act since NRC is obligated to enforce the EPA general standards. However, the precise limits of EPA's general standard-setting authority are uncertain. In this "gray area" there is a potential for confusion and overlap. In the uranium fuel cycle area, the limits of authority are now defined. In the nuclear waste management area, the precise limits are as yet to be defined.

On December 6, 1976, EPA published an Advance Notice of Proposed Rulemaking (41 FR 53363) in which it announced its intent to develop environmental radiation protection standards for high-level radioactive wastes to assure protection of the public health and the general environment from these wastes. In its notice, EPA stated that it intended to develop applicable environmental criteria for all radioactive wastes and that in the development of these criteria and standards it would consider all currently available information on long-term implications of radioactive wastes and the risks associated with such wastes. The EPA notice announced that the subject would be discussed in depth at a series of workshops and requested pertinent information respecting the following matters:

> The capability of various types of source encapsulation to retain high activity wastes or long-lived alpha wastes for long periods.
>
> The geologic media that may be used to contain high activity wastes, long-lived alpha wastes, or combined wastes and the retention capabilities of those media over long periods of time.
>
> Predictions of the most likely transfer co-efficients of radioactive material for selected combinations of source encapsulation, engineering containerization, geologic media, and predicted environmental levels for long periods of time.
>
> The probability and risks associated with accidental disturbances, either occurring naturally or as a result of institutional failures, and the impact of these risks on the predictions mentioned above.
>
> Factors important to providing reasonable assurance that environmental protection standards can be satisfied and that methods are available to implement environmental protection standards.

---

[1] Available in committee files.

In the exercise of its statutory responsibilities for licensing and regulating nuclear power plants as well as other production and utilization facilities, for licensing and regulating certain ERDA facilities and for licensing and regulating special nuclear material, byproduct material and source material, NRC is actively engaged in developing criteria for use in licensing radioactive waste repositories which will assure that those repositories are constructed and operated in a manner which will preserve the common defense and security and protect the health and safety of the public. In connection with this regulatory program, NRC has underway a series of in-depth studies in many of the same areas in wihch EPA has announced its intent to conduct studies and investigations. In consequence, duplicative investigations which have a potential for yielding conflicting conclusions are currently in progress in the same substantive areas.

(*b*) *Transferred FRC functions*

The functions of the Federal Radiation Council as specified in its organic act[2] and transferred to the Environmental Protection Agency are to ". . . consult qualified scientists and experts in radiation matters, . . . and qualified experts in the field of biology and medicine and in the field of health physics. . . ." to ". . . advise the President with respect to radiation matters, directly or indirectly affecting health, including guidance for all Federal agencies in the formulation of radiation standards and in the establishment and execution of programs of cooperation with States. . . ." and to ". . . perform such other functions as the President may assign to it by Executive order. . . ." This statutory authority was designed to furnish a mechanism which would enable the President, on the basis of objective, independent advice reflecting the best scientific knowledge as well as policy considerations, to issue guidance to all Federal agencies which would assure uniformity and eliminate diversity in federal radiation standards. Although recommendations made by EPA in the exercise of this statutory authority are only advisory, once the President has approved these recommendations as guidance, it has generally been understood that federal agencies may not promulgate standards and regulations under their existing statutory authority which are inconsistent with that guidance.

Pursuant to its transferred FRC authority, EPA is engaged in reviewing Federal Radiation Protection Guides (25 FR 4402–4403, May 18, 1960) with a view to preparing revised recommendations for submission to the President for his approval and subsequent issuance as guidance to Federal agencies. In conducting these reviews, EPA has sought the counsel and advice of other Federal agencies, including NRC. At the present time, for example, a representative from NRC is serving on the Interagency Committee on Federal Guidance for Occupational Exposures to Ionizing Radiation established by EPA to develop recommendations on occupational radiation exposures. A representative from NRC is also serving on an Interagency Liaison Committee which is working with EPA to develop guidelines for the cleanup of plutonium and other transuranium elements and the restoration of contaminated areas. The objective of these guidelines is to set a level or levels of soil contamination above which cleanup is recommended. NRC, as well as other members of the Federal Interagency Central Coordinating Committee for Radiological Emergency Preparedness, has provided comments to EPA on proposed nuclear accident protective action guides for airborne release of radioactive gases and particulates. These Protective Action Guides are being prepared for use of Federal Agencies and States in emergency planning for accidents at fixed nuclear facilities and during transportation of nuclear materials. These interagency committees provide forums for the resolution of differences regarding the appropriate radiation standards. Following issuance of EPA recommendations as Presidential guidance, it is incumbent on NRC to review and amend its regulations as appropriate to bring them into conformity with this guidance. In this way, any potential conflict between NRC's regulatory authority and EPA's FRC authority to make recommendations regarding radiation standards is effectively resolved. However, in many cases both NRC and EPA would be authorized to conduct the same activities—NRC in the course of developing its own regulations (e.g., emergency preparedness requirements) and EPA in the course of developing guidance on radiation protection standards.

---

[2] Public Law 86–373, 73 Stat. 688, 1959, Sec. 274h. of the Atomic Energy Act of 1954, as amended, 42 U.S.C. 2021(h).

On August 31, 1976, EPA published proposed regulations for State underground injection control programs (40 CFR Part 146; 41 FR 36730–36745, August 31, 1976). Although the statutory concepts of "underground injection" and "subsurface emplacement of fluids by well injection" were discussed at some length in the Federal Register notice, the issue of whether these concepts include emplacement below the surface of high-level or other radioactive wastes was not addressed.

2. *Safe Drinking Water Act, Public Law 93–523, December 16, 1974, 88 Stat. 1661, as amended, 42 U.S.C.A. §§ 300f–300j–9*

Part C of the Safe Drinking Water Act establishes a system of Federal-State controls to prevent underground injection which endangers drinking water sources. Under the provisions of the Act, State underground injection control programs must meet certain minimum requirements to secure federal approval, including the requirement that they prohibit any underground injection not authorized by State permit or State rule. The Act defines "underground injection" as the "subsurface emplacement of fluids by well injection." The Act further provides that underground injection shall be considered to endanger drinking water sources ". . . if such injection may result in the presence in underground water which supplies or can reasonably be expected to supply any public water system of any contaminant, and if the presence of such contaminant may result in such system's not complying with any national primary drinking water regulation or may otherwise adversely affect the health of persons." The term "contaminant" as used in the Act means "any physical, chemical, biological, or radiological substance or matter in water. . . ." Under this definition, special nuclear material, byproduct material and source material regulated by NRC would be considered contaminants. Whether there is a potential conflict between the provisions of the Atomic Energy Act of 1954, as amended, and the provisions of Part C of the Safe Drinking Water Act which authorize States to conduct underground injection permit programs depends on the manner in which the statutory definition of "underground injection" is interpreted. The potential scope of this defintion is rather broad and could conceivably include the emplacement below the surface of high-level or other radioactive wastes.

3. *Occupational Health and Safety*

In 1970, Congress enacted the Occupational Safety and Health Act of 1970 (Pub. L. 91–596, December 29, 1970, 84 Stat. 1590, 29 U.S.C. §§ 651 et seq.) to assure safe and healthful working conditions for working men and women. Section 4(b)(1) (29 U.S.C.A. § 653(b)(1)) of that Act states: "Nothing in this Act shall apply to working conditions of employees with respect to which other Federal agencies, and State agencies acting under section 274 of the Atomic Energy Act of 1954, as amended (42 U.S.C. 2021), exercise statutory authority to prescribe or enforce standards or regulations affecting occupational safety or health."

OSHA regulations specifically provide that employers who possess or use source material, byproduct material or special nuclear material under NRC or Agreement State licenses shall be deemed to be in compliance with OSHA regulations with respect to such possession and use (29 CFR § 1910.96(p).) Each year, NRC routinely makes a redetermination of continuing compatibility and adequacy of Agreement State regulatory programs. The U.S. Department of Labor has agreed to accept NRC's determination in lieu of their making independent investigations and determinations on safe working conditions for radiation workers in Agreement State licensee establishments under the Occupational Safety and Health Act of 1970.

Despite these procedures, uncertainty as to whether an overexposure in the workplace was occasioned by agreement materials (i.e., source material, byproduct material and special nuclear material in quantities not sufficient to form a critical mass) non-agreement sources of radiation or some combination of the two has resulted in the past in some overlapping in enforcement actions taken under State Agreements with the Nuclear Regulatory Commission and under OSHA-approved State plans. Following a meeting between NRC and OSHA staff members, an understanding was reached that violations arising from noncompliance with Agreement State radiation control regulations for agreement materials would be cited against the Agreement State radiation control regulations and violations of occupational safety and health standards for nonagreement sources of radiation would be cited under appropriate OSHA standards and procedures in those States which have OSHA approved State plans. A further u[illegible]rstanding was reached that citations would be predicated upon a determin[illegible]on of whether agreement materials or nonagreement sources of radiation were the major contributor to the violation.

II. FLOATING NUCLEAR POWER PLANTS AND NUCLEAR POWER ELECTRIC GENERATING STATIONS LOCATED ON COASTAL AND INLAND NAVIGABLE WATERS

A. U.S. COAST GUARD—NRC

On January 4, 1974, the former Atomic Energy Commission and the United States Coast Guard entered into a Memorandum of Understanding for the Regulation of Floating Nuclear Power Plants (39 FR 2124, January 17, 1974). (As defined in the Memorandum of Understanding a "floating nuclear power plant" is "a nuclear powerplant, mounted on and thereby integrally with a barge, fabricated at a central shipyard facility, then towed to a fixed position where it is installed and moored, nuclear fuel is loaded, and where it is operated as a floating facility to supply electrical energy into an onshore electrical load network.") The Memorandum of Understanding, which remains in effect and is adhere to by NRC, specifies detailed procedures under which the respective statutory responsibilitities of both agencies for the regulation of safety and protection of the environment from effects of construction and operation of floating nuclear power plants are to be exercised. (These statutory authorities are described in detail in section 2 of the Memorandum.) The Memorandum also identifies with particularity those aspects of floating nuclear power plants of primary concern to each agency and of joint concern to both agencies.

The purpose of the Memorandum, as stated herein, is to coordinate and implement consistent and comprehensive requirements to maximize safety with respect to the design, fabrication, construction and operation of floating nuclear power plants, to minimize the possible adverse environmental impact of such plants, and to minimize duplication and avoid possible inconsistency in safety requirements applied to such plants.

When the AEC and the U.S. Coast Guard began the negotiations which led to the preparation and execution of the Memorandum of Understanding, it was readily apparent that there were extensive areas of overlap and potential conflict with respect to their respective responsibilities for floating nuclear power plants. To date, NRC has found the Memorandum effective in achieving its objective of providing an orderly framework within which the regulatory responsibilities of the NRC and the U.S. Coast Guard with respect to floating nuclear power plants can be carried out in an efficient and consistent manner.

We would expect similar problems to arise in connection with the regulation of the construction and use of nuclear-powered merchant ships. NRC and the U.S. Coast Guard are presently engaged in discussions concerning memoranda of understanding to clarify their respective responsibilities in this area, including responsibilities relating to the presentaton of U.S. views regarding the safety of nuclear-powered merchant ships in such international forums as the Intergovernmental Maritime Consultative Organization (IMCO) and the Nuclear Energy Agency of the Organization for Economic Cooperation and Development (NEA/OECD).

B. U.S. ARMY CORPS OF ENGINEERS—NRC

Similar concerns regarding the impact of the regulatory authority of the U.S. Army Corps of Engineers over the construction of structures in navigable waters of the United States upon nuclear power electric generating stations, including floating nulear power plants, located on coastal and inland navigable waters and at offshore sites led the Nuclear Regulatory Commission and The Corps of Engineers to enter into a Memorandum of Understanding on July 2, 1975. (40 FR 37110, August 25, 1977. The purpose of this Memorandum of Understanding is to provide for the coordination and implementation of consistent and comprehensive requirements to assure effective, efficient and thorough regulation of nuclear power plants and to avoid conflicting and unnecessary duplication of effort and of standards related to overall public health and safety and environmental protection. The Memorandum details the relevant statutory authorities of each agency (sec. 2)[3] and describes the manner in which their respective responsibilities for issuing permits and licenses (sec. 4), taking enforcement actions (sec. 3), preparing environmental impact statements (sec. 3), conducting inspections (secs. 3b, 5d, e), reviews (sec. 5c, e), and public hearings (sec. 3c) will be carried out. Based on experience to date, NRC has found the procedures specified in the Memorandum effective in eliminating or minimizing areas of potential conflict between The Corps of Engineers and NRC and in enhancing the efficiency and effectiveness of their respective regulatory activities.

---

[3] In the case of the U.S. Army Corps of Engineers, these statutory authorities include, among others, Section 404 of the Federal Water Pollution Control Act Amendments of 1972 and the Marine Protection, Research and Sanctuaries Act of 1972 which relates to ocean dumping.

III. TRANSPORTATION

Despite enactment of the Hazardous Materials Transportation Act in 1975, there has been little change since 1968 in the respective responsibilities of the U.S. Department of Transportation and the former Atomic Energy Commission (now the Nuclear Regulatory Commission) with respect to safety in the transportation of byproduct, source and special nuclear material on land in interstate and foreign commerce. As explained more fully herein, the continuing need to develop and implement consistent, comprehensive and effective regulations and to avoid duplication of effort led these agencies, on March 22, 1973, to enter into a revised Memorandum of Understanding which is presently in effect.

The licensing and related regulatory authority assumed by the U.S. Nuclear Regulatory Commission upon its establishment January 19, 1975 pursuant to section 201 of the Energy Reorganization Act, as amended[4], included authority to license and regulate[5], in a manner which will protect the environment[6], promote the common defense and security and protect the public from the standpoint of radiological health and safety, the receipt, possession, use and transfer, including packaging, shipment and transportation, of byproduct material, source material and special nuclear material as defined in sections 11e, z and aa of the Atomic Energy Act of 1954, as amended. (42 U.S.C. 2014(e), (z), (aa)).

Since most shipments of radioactive materials move in routine commerce on conventional transportation equipment and are subject to the same transportation environment, including accidents, as non-radioactive cargo, the NRC, in exercising its regulatory responsibilities under the Atomic Energy Act of 1954, as amended, has placed primary reliance on packaging to assure safety in transport. To make certain that only those shipments of radioactive materials which are safe enough to withstand transportation hazards without detriment to the health and safety of the public are delivered to a carrier for transport, the NRC has promulgated and continuously monitors compliance with detailed regulations pertaining to procedures and standards for packaging, labeling, and shipment of radioactive material (10 CFR Part 20, Standards for Protection Against Radiation, and Part 71, Packaging of Radioactive Material for Transport and Transportation of Radioactive Material under Certain Conditions). The NRC has also promulgated and monitors compliance with detailed regulations for the physical protection, including physical protection during transportation, of certain quantities of strategic special nuclear material (see generally 10 CFR Part 73, Physical Protection of Plants and Materials).

NRC safety standards for packages used in the transportation of radioactive materials (10 CFR Part 71) are applicable to packages used in all modes of transport. These standards and regulations are directed primarily towards assuring that packaging for radioactive materials is designed and constructed to maintain, under both normal and accident conditions over its useful lifetime, the necessary design integrity, considering the type, form and quantity of radioactive contents, to prevent a significant loss of radioactive material from a package or a significant increase in radiation levels from a package, to assure nuclear criticality safety, and to provide adequate heat removal. These standards reflect two basic considerations: (1) protection of the public from external radiation, and (2) assurance that either the radioactive contents of the package are unlikely to be released during normal or accident conditions of transport or, if the container is not designed to withstand accidents, the contents are so limited in quantity as to preclude a significant safety problem if released.

[4] Pub. Law 93–438, 88 Stat. 1233 at 1242, as amended by Pub. Law 94–79, 89 Stat. 413–414 (42 U.S.C. 5841).

[5] See. for example, secs. 53, 57, 62, 63, 69 and 81 (42 U.S.C. 2073, 2077, 2092, 2093, 2099 and 2111) which authorize the issuance of licenses to, among other things, receive, possess and transfer special nuclear material, source material and byproduct material and sec. 161 (b) (42 U.S.C. 2201(b)) which authorizes the establishment "by rule, regulation or order [of] such standards and instructions to govern the possession and use of . . . [these materials] as the Commission may deem necessary or desirable to promote the common defense and security or to protect health or to minimize danger to life or property."

[6] Pursuant to the National Environmental Policy Act of 1969, Pub. Law 91–190, 83 Stat. 852–856, 42 U.S.C. Ch. 55.

In addition to safety standards for packages, NRC regulations also include procedural controls applicable to the use of shipping containers. In particular, NRC regulations provide that NRC licensed materials may not be transported or delivered to a carrier for transport unless the licensee complies with applicable Department of Transportation (DOT) regulations and the shipment is authorized by a general or specific NRC license or is exempted from this license requirement by NRC regulations (10 CFR §§ 71.3, 71.5). Under the provisions of the general license contained in § 71.12 of NRC's regulations (10 CFR § 71.12) NRC licensed materials may be delivered to a carrier for transport in previously approved containers. NRC regulations also contain detailed procedures for opening and closing packages and for inspection of packages both before and after the first and each subsequent use (see generally 10 CFR § 20.205 and §§ 71.51–71.63).

Since its establishment in 1966, the U.S. Department of Transportation has had broad responsibility for transportation safety, including continuing and increasing authority to regulate the transportation of explosives, and other hazardous materials, including radioactive materials. This authority, which overlaps that of the Nuclear Regulatory Commission with respect to safety in the transportation of byproduct, source and special nuclear material on land in interstate and foreign commerce, is exercised pursuant to the Transportation of Explosives Act (18 U.S.C. 831–835), the Dangerous Cargo Act (R.S. 4472, as amended, 46 U.S.C. 170), Title VI and section 902(h) of the Federal Aviation Act of 1958 (49 U.S.C. 1421–1430 and 1472(h)) and most recently pursuant to the Transportation Safety Act of 1974, particularly Title I of that Act entitled the Hazardous Materials Transportation Act (49 U.S.C. 1801–1812). DOT authority includes authority formerly vested in the Interstate Commerce Commission under the provisions of the Transportation of Explosives Act which was expressly transferred to the Secretary of Transportation by Congress in 1966 (49 U.S.C. 1655(e)(4)).

Under the provisions of the Transportation of Explosives Act, which extend the authority of the Department of Transportation to land shipments and carriers in interstate commerce, the Secretary of Transportation is authorized to formulate regulations for the safe transportation of radioactive materials "which shall be binding upon all carriers engaged in interstate or foreiegn commerce" (18 U.S.C. 834(a)) and which "shall be in accord with the best-known practicable means for securing safety in transit, covering the packing, marking, loading, handling while in transit, and the precautions necessary to determine whether the material when offered is in proper condition to transport." (18 U.S.C. 834(c)). The Transportation of Explosives Act (18 U.S.C. 843 (b)) also contains an express requirement that the Department of Transportation advise and consult with the Nuclear Regulatory Commission before adopting any regulations relating to radioactive materials. (As noted earlier, the responsibilities of the Interstate Commerce Commission under this Act been transferred to the Department of Transportation.)

The authority of the Secretary of Transportation under the Transportation of Explosives Act has been strengthened by the provisions of the Hazardous Materials Transportation Act (49 U.S.C. 1801–1812) which empower the Secretary to promulgate and enforce uniform hazardous materials regulations for all modes of transportation. Pursuant to this authority, the Secretary is authorized to promulgate "regulations for the safe transportation in commerce of hazardous materials . . . [which] shall be applicable to any person who transports, or causes to be transported or shipped, a hazardous material, or who manufactures, . . . repairs, or tests a package or container . . . certified, or sold . . . for use in the transportation . . . of certain hazardous materials." These regulations "may govern any safety aspect of the transportation of hazardous materials which the Secretary deems necessary or appropriate, including . . . [among other things,] packing, . . . handling, labeling, . . . placarding, and routing . . ." (49 U.S.C. 1804(a)). Before issuing any regulations with respect to the routing of hazardous materials, the Secretary of Transportation is required by section 105(b) of the Hazardous Materials Transportation Act (49 U.S.C. 1804(b)) to consult with representatives of the Interstate Commerce Commission. Once those regulations have been adopted, the Interstate Commerce Commission is obligated to implement them to the extent of its lawful authority.

In the exercise of this broad authority, the Department of Transportation has promulgated extensive regulations, codified in 49 CFR Parts 170–189, pertaining to certain types of packaging, labeling and conditions of carriage. These regulations provide controls over the handling, stowage and storage of radioactive materials by carrier personnel and other cargo handlers. The regulations also set forth basic package performance, design and use requirements, and specify standards for marking and labeling radioactive material packages and for the preparation of standardized shipping papers which identify the basic characteristics of the radioactive material packages.

In 1966, in order to develop and implement consistent, comprehensive and effective regulations for the safe transport of radioactive material and to avoid duplication of effort, the Department of Transportation and the former Atomic Energy Commission (now the Nuclear Regulatory Commission) entered into a Memorandum of Understanding.[7] On March 22, 1973, a revised Memorandum of Understanding was signed which is presently in effect. (38 FR 8466, April 2, 1973, copy attached.) Under the provisions of this Memorandum of Understanding, the NRC develops safety standards for packaging design and performance for packages of fissile material and for Type B and large quantities of radioactive material and evaluates designs for containers for these materials. DOT is responsible for developing safety standards for packaging design and performance for all other types of radioactive material packages used in transportation and for evaluating designs for those packages.

DOT is also responsible for developing safety standards governing mechanical conditions of carrier equipment and qualifications of carrier personnel, carrier loading, unloading, handling and storage of radioactive material, and any special transport controls to be provided during carriage, including construction standards for transport vehicles. The Memorandum of Understanding also contains mutual undertakings whereby NRC will adopt regulations requiring NRC licensees not otherwise subject to DOT regulations to comply with the applicable requirements of those regulations when transporting or shipping radioactive material, and DOT will adopt regulations imposing on shippers and carriers subject to its jurisdiction and not otherwise subject to NRC regulations requirements comparable to those contained in NRC regulations. The Memorandum of Understanding also provides that each agency shall conduct an inspection and enforcement program within its jurisdiction, that DOT will be the lead agency in investigating accidents and suspected leakage from radioactive material packages occurring during transit and that NRC will be the lead agency in conducting such investigations when the accidents or suspected leakage occur prior to or after transit.

To date NRC has found the Memorandum of Understading effective in providing an orderly framework in which the regulatory responsibilities of the NRC and the U.S. Department of Transportation can be carried out in an efficient and consistent manner.

IV. NUCLEAR MEDICINE

In the field of nuclear medicine, there are several areas in which the regulatory authority of the Nuclear Regulatory Commission is affected by the statutory responsibilities of other federal agencies.[8] While some of the areas of concern are of long standing, the announcement in 1974 by the Food and Drug Administration of its intention to terminate the exemption for AEC controlled drugs and the subsequent enactment of the Medical Device Amendments of 1976 have made the need to develop consistent regulations and avoid duplicative regulatory controls acute. The Commission is currently engaged in a comprehensive review of its regulatory policies and practices in an effort to determine how these concerns may best be resolved and to clarify NRC's role in the regulation of nuclear medicine.

Under the provisions of the Atomic Energy Act of 1954, as amended, the NRC is empowered to regulate the manufacture, distribution and clinical use of byproduct, source and special nuclear material by means of a licensing program in which the Commission licenses the possession and use of such materials by manufacturers, distributors, pharmacies, researchers, medical institutions and private physicians. The objective of this regulatory scheme is to protect the health and safety of the worker, the patient and the general public in the medical uses of byproduct, source and special nuclear material. In accordance with this authority, NRC now regulates virtually all aspects of the radiation safety of the workers and the general public and certain aspects of the safety and efficacy of radioactive drugs and devices containing these materials with respect to the patients.

---

[7] The Memorandum of Understanding was initially entered into between the Interstate Commerce Commission and the Atomic Energy Commission on March 21, 1966. On April 1, 1967, the Department of Transportation assumed the functions and responsibilities of the Interstate Commerce Commission under the Memorandum of Understanding.

[8] The Social Security Administration, for example, controls medical services, including the medical use of radioisotopes, by controlling the reimbursement process for Medicare and Medicaid.

For many years, the former AEC, in consultation with its Advisory Committee on the Medical Uses of Radioisotopes, regulated the safety and efficacy of radioactive drugs and devices with respect to the patient. During this period, the Food and Drug Administration, which is recognized as the lead agency in regulating nuclear medicine, was not empowered to regulate radioactive devices and expressly exempted radioactive drugs controlled by the AEC from its regulatory authority. In 1974, the FDA announced its intention to terminate the exemption for AEC-controlled drugs and the AEC withdrew from regulating the safety efficacy of radioactive drugs. However, the AEC, now NRC, continued to evaluate the safety and efficacy with respect to the patient of certain devices, for example bone mineral analyzers, Pu-238 pacemakers and brachytherapy sources.

The Federal Food, Drug and Cosmetic Act of 1938 (42 U.S.C.A. §§ 301 et seq.) authorized the Food and Drug Administration to regulate the safety of drugs offered for interstate commerce through control of product labeling. Legislative amendments in 1962 gave the FDA tighter controls over drug safety and introduced controls over the efficacy of drugs to foreclose the marketing of safe, adequately labeled drugs that do not work. The Federal Food, Drug and Cosmetic Act of 1938, as amended, also authorized the FDA to control the manufacture of drugs, including radioactive drugs. In 1976, Congress enacted the Medical Device Amendments of 1976, (Public Law 94-295, May 28, 1976, 90 Stat. 539-583) which gave the Food and Drug Administration authority to regulate medical devices similar to its authority to regulate the safety and efficacy of drugs.

In carrying out its statutory responsibilities, FDA employs a system of pre-market approval for drugs and pre-market approval, performance standards or general controls for medical devices. Under this regulatory scheme, FDA requires drug manufacturers to carry out extensive investigational programs to establish the safety and efficacy of new drugs or of new uses of drugs previously approved for other uses before these new drugs or new uses are approved for routine use. During this investigational stage, FDA exercises regulatory control over the use of radioactive drugs and devices.

Although Congress clearly required the FDA to control the availability of drugs for prescribing physicians, it did not intend FDA to regulate or interfere with the practice of medicine. Accordingly, Congress did not give FDA statutory authority to regulate the use of drugs after their approval for routine use. Instead, Congress limited FDA's responsibiilties to determining the safety and effectiveness of durgs and the truthfulness of their labeling. Final judgment as to which, if any, of the available drugs a patient should receive, remained the responsibility of the physician to be exercised by the physician in the light of the information contained on the drug label and other data available to him.

U.S. ENERGY RESEARCH AND DEVELOPMENT ADMINISTRATION,
Washington, D.C., June 17, 1977.

Hon. ADLAI E. STEVENSON,
Chairman, Science, Technology and Space Subcommittee, Committee on Commerce, Science, and Transportation, U.S. Senate.

DEAR SENATOR STEVENSON: This is in response to your letter of May 19, 1977, to Robert W. Fri, Acting Administrator, U.S. Energy Research and Development Administration (ERDA), concerning Radiation Health and Safety Research.

In accordance with guidance from your staff, we have used your format and matrix to report the following programs under the direction of the Assistant Administrator for Environment and Safety (AES) of ERDA.

Biomedical and Environmental Research (Nuclear Program).

Operational and Enviromental Safety (Part).

Enclosed is an overall summary of the Biomedical and Environmental Nuclear Research program as well as summarizations for each of the following research areas:

Human Health Studies/Health Effects Research in Biological Systems (combined as Health Effects of Nuclear Technologies).

Environmental Studies.

Physical and Technological Studies.

Biomedical Applications (Medical Diagnostic Therapeutic).

Criteria and/or Standards Development.

Surveillance of Facilities and Sites (Monitoring and/or Surveillance).

We have also enclosed responses to each of your questions.

We regret to inform you that our records are not maintained in a manner to supply detailed manpower data but recent experience indicates a cost per scientific man-year of approximately $60,000–$65,000.

If you have any questions concerning this data, please contact my office.

Sincerely,

JAMES L. LIVERMAN,
Assistant Administrator for Environment and Safety.

DIVISION OF BIOMEDICAL AND ENVIRONMENTAL RESEARCH RADIATION EFFECTS RESEARCH

The Division of Biomedical and Environmental Research (BER) has been the primary source for support of research on health and environmental effects of radiation in the Federal government. As a program division under the Assistant Administrator for Environment and Safety (AES), the entire research support of BER was focused on the effects of radiation on man and his environment. The research program included, in addition to applied effects research, (1) support of more fundamental research on the normal structure and function of key biological molecules (e.g., DNA), tissues and organ systems which are sensitive to radiation effects; and (2) support of studies to develop new and improved instrumentation and techniques for the beneficial application of radiation and radioisotopes in medicine, agriculture and biological research.

Although BER has no regulatory responsibilities, the results of this research effort provided a vast amount of data which was used by national and international organizations in recommending standards for human exposure to radiation. In addition, the same data was used to ensure that the development of nuclear energy technologies (both weapons and power reactors) were conducted with maximum safety for individuals in the occupational work forces and the general population.

With the establishment of the Energy Research and Development Administration (ERDA), BER redirected a significant fraction of its research support into the nonnuclear area to be responsive to its new mission in support of all energy technology developments. Since BER is still the primary source of funds in support of radiation effects research in the Federal government,[1] this redirection of research effort, of necessity, required that work in the nuclear research area be critically reviewed, and all projects which were considered to be of lowest priority or near completion were redirected into support of nonnuclear energy technology development. We are continuing to support high priority nuclear energy-related research projects, focusing primarily on the long-term late effects of low dose, low dose-rate exposure of man.

Because of this redirection in research support, the percentage of nuclear-related research supported by BER in fiscal year 1976 decreased significantly from that in fiscal year 1975. In addition, two new categories of research (Multi-Technology and General Science) were created. The Multi-Technology category incorporated research which had been supported to resolve health and environmental problems related to nuclear-energy technology development needs, but were equally applicable to nonnuclear technology development (e.g., research on the effects of thermal effluents on environmental biota, environmental studies (base-line) in off-shore coastal regions of importance in energy-related activities). The General Science category included research that was in support of health and environmental research on the effects of energy-related pollutants on man and environmental biota. This research provides essential information about the complex functional systems (both organismal and ecosystem) that are subject to damage by energy-related pollutants.

---

[1] The Nuclear Regulatory Commission supports research in the nuclear area for confirmatory assessment of nuclear-reactor safety which does not overlap BER-supported research.

RESEARCH ON THE POTENTIAL HEALTH EFFECTS OF NUCLEAR TECHNOLOGIES

Part I. Program Justification

A. INTRODUCTION

The Energy Research and Development Administration (ERDA) National Energy Plan emphasizes nuclear energy as one of the most important technologies required to meet energy needs of the Nation in each of the three time frames considered (near-term, 1975–1985; mid-term, 1985–2000; and long-term beyond 2000). During the near-term and mid-term periods emphasis will be placed on overcoming the technological and environmental problems inhibiting expansion of highly utilizable existing nuclear systems—notably light water nuclear reactors. In the long-term period, major emphasis is placed on the successful development of fusion and breeder nuclear reactors.

While the present amount of information on the health effects of radiation and radioactive materials is extensive compared to that available for most other energy effluents, not all problems have been solved or even fully addressed. In addition, challenges have been raised concerning the long-term impact of processes associated with the nuclear fuel cycle on human health. These challenges are particularly concerned with the potential biological effects of very low doses delivered at very low dose rates to large populations and the potential toxicity of plutonium and other alpha-emitting radionuclides.

B. NUCLEAR TECHNOLOGIES

1. Nuclear fission

The ERDA National Plan for Energy Research, Development, and Demonstration (ERDA 76–1) listed three nuclear technologies as being of "Highest Priority Supply." The near-term major energy systems are the light water (converter) reactors, which presently supply about 8% of the total electrical energy production and 2 percent of total energy production in the United States. Nuclear technologies providing nearly "inexhaustable" energy sources for the future are the developing breeder reactors and fusion systems.

There are many aspects of operation common to the breeder and converter (light water) reactor systems. The types of radioactive materials that may be used for fuel and those which are produced depend more upon the particular fuel cycle than on whether a reactor is a breeder (i.e., produces more fuel than it consumes) or is a converter (produces some new fuel, but less than it consumes). There are only two feasible fuel cycles when grouped as to fertile material; these are the uranium and thorium fuel cycles. Both are intially driven by uranium isotopes, but may develop a variety of fertile fissle combinations. The two cycles are summarized as:

Cycle	Fertile nuclide	Fissile nuclide(s)	Sample of reactor type
Uranium	U–^{238}	U–^{235}, Pu–^{239}	Light water reactor, light water reactor with plutonium recycle, and liquid metal fast breader reactor.
Thorium	Th–^{232}	U–^{233}	Light water breeder reactor.

Under certain conditions it is possible to make more fissile material than is consumed with either cycle, in which case the reactor is called a breeder. Combinations of the two cycles are also possible, as is the case for the present High Temperature Gas Reactor (HTGR).

In the uranium cycle, Pu–239 is produced following neutron capture by U–238, and in the process other plutonium isotopes as well as nuclides of americium and curium are generated, together with fission products and activation products of the materials of which the reactor is constructed. In the thorium cycle, U–233 is produced following neutron capture by Th–232. Breeder reactors are designed to extract much more of the total energy from the available fertile material. In the case of uranium this extends by 100-fold the useful energy from uranium already mined or recoverable from proven reserves. In addition, it would be feasible to utilize depleted uranium in the "tailings" from the enrichment plant. Since thorium is a more abundant element than uranium, the energy made available by breeder reactors is even larger. To date the only peaceful nuclear technology that has been introduced on a large scale is the light water reactor. It has also been deemed appropriate, based on current knowledge, to proceed with technological development of demonstration plants of the Liquid Metal Fast Breeder Reactor (LMFBR). A pending decision by the Nuclear Regulatory Commission (NRC) on the use of plutonium as recycle fuel in light water reactors is a major decision as it involves the recovery, handling, fabrication, and the use of plutonium having an isotopic composition very similar to that expected in the LMFBR.

Regardless of the reactor type and fuel used in nuclear fission reactors, the fuel cycle and attendant potential health effects will be similar. The major components of the fuel cycle are mining, fuel fabrication, reactor operation, fuel reprocessing, transportation, and waste handling and storage.

Radiation exposure incident to the development and operation of the technologies can be grouped as internal and external exposures. The external exposures consist of exposure to neutron and gamma radiation. Internal deposition of radionuclides produced and/or handled in the nuclear fuel cycle by man is probably of the greatest concern.

2. *Nuclear fusion*

With respect to nuclear fusion it is premature to identify the health-related research needs in detail. However, current research in support of fission problems will address some of these needs, particularly potential external exposure to gamma rays and internal exposure to tritium. There may be a number of activation products (e.g., niobium) for which we have too little information and which will require further definitive research. These materials will probably include electron capture and positron emitting nuclides which have not been well studied thus far. The biological effects of electromagnetic fields which may be associated with fusion reactors are not well understood at the present time. It is certain that specific research needs will be identified as the technology becomes more advanced and as demonstration plants are put into operation.

C. PLANNING AND ESTABLISHMENT OF PRIORITIES

Plans which allow rapid development of these nuclear technologies must include:

1. Establishment of health research priorities which are coordinated with the development and expansion of the technology.
2. Appraisal and correlation of the national effort in health research in order to efficiently obtain the required information.

Planning to assess the potential health and environmental consequences of developing technologies was initiated in 1973, as part of preparation for Dr. Dixie Lee Ray's report to the President, "The Nation's Energy Future," (WASH–1281). In early 1974 an interagency working group was convened to conduct a similar study of research needs in "Health and Environmental Effects of Energy Use." This planning study resulted in a report prepared for the Council on Environmental Quality (CEQ) and the Office of Management and Budget (OMB) in November 1974, referred to informally as the King-Muir report. These studies involved panels of experts and representatives of science, technology, and government agencies involved in energy-related environmental and health research. The plan and the report incorporate the consensus of research needs and priorities, and describe what the various agencies are funding in energy-related research.

The major research effort on the health effects of ionizing radiation was sponsored by the Atomic Energy Commission (AEC). Advice in identifying areas of needed research was sought and obtained from a variety of sources including the National Academy of Sciences (NAS), the International Commission on Radiological Protection (ICRP), and the National Council on Radiation Protection and Measurements (NCRP). These bodies will continue to be a source of advice for the ERDA.

There has been a gradual shift in research emphasis from concern with the health effects of fallout from atmospheric testing of weapons to the concerns associated with potential health effects of nuclear power production. Many of these concerns have been emphasized in the environmental impact statements for the LMFBR and mixed oxide fuel recycle for light water reactors. Since one of the major challenges of these statements has been based on the concerns for the health and environmental impacts of the transuranic radionuclides, a special working group [the Transuranium Technical Group (TTG)] has been organized. This group, which reports directly to the Assistant Administrator for Environment and Safety, periodically evaluates the current needs for research on the actinide elements. In addition, the Manager of the Biomedical Programs, Division of Biomedical and Environmental Research (BER), has a smaller panel of reviewers which evaluates and recommends research needed on the potential health effects of long-term, low-level irradiation from either external or internal sources.

These efforts have resulted in the establishment of program priorities based on the following criteria: (1) severity of potential health effects, (2) magnitude of the problem (size of population exposed), (3) need for information, and (4) urgency for information.

Part II. Program Overview

Research in the Health Studies category is conducted primarily to define and quantify the impact of energy technologies on human health. To accomplish this goal, it is necessary to (1) identify hazardous energy-related physical and chemical agents, (2) identify adverse human effects induced by these hazardous agents and development and understanding of the pathophysiological basis for such effects, (3) Develop methods for the early detection and diagnosis of energy-related health effects, (4) Obtain quantitative data on dose-effect relationships in humans and several animal species, (5) integrate the quantitative data from the different animals into predictive models that can be used to estimate human health risks under a variety of exposure conditions, and (6) develop improved modes of protection and remediation.

This comprehensive research program on the potential hazards associated with the production of energy from nuclear reactors will provide the data needed to establish and refine guidelines with respect to exposure of persons to ionizing radiation. It will also provide a foundation on which to base cost/risk/benefit analyses relative to health effects.

In regard to existing and developing nuclear technologies, research emphasis centers on evaluating health risks arising from exposures to low levels of external radiation or to radionuclides that may occur in work areas or in the general environment at particular stages of the nuclear energy cycle. Inhalation exposure to radionuclides is considered the most significant potential exposure modality and is receiving major emphasis.

The study of interactive effects occurring when biological systems are exposed to combinations of radionuclides and/or other hazardous agents in addition to radiation is of great importance and will be given high priority. Studies of low doses and dose rates are currently being emphasized because these are the modalities most likely to be encountered in exposure of the general public, and few data are presently available. Late effects including life-shortening, mutations, cancer, and impairment of growth or development will be of primary interest.

Whenever possible, data on potential health risks must be obtained from humans who have been exposed accidentally, occupationally or medically to ionizing radiation. It is essential also to obtain human information on the metabolism and deposition of radionuclides generated and/or utilized in nuclear technologies as the basis for estimating the dose to organs at risk from such materials.

Two of the more important bodies of human data are being developed by the Radiation Effects Research Foundation (RERF) (the former Atomic Bomb Casualty Commission, Japan) (ABCC), and by the Center for Human Radiobiology at Argonne National Laboratory (ANL) (the data for radium in man). The former are more applicable to short exposures of gamma rays and neutrons to the whole body, the latter are more applicable to the prolonged alpha radiation of bone or of epithelial cells that may result from internally deposited uranium, thorium, plutonim, and the other transuranic elements. Because the data available for man are limited, controlled animal experimentation must be used to obtain detailed information about the kinetics and mechanisms of radionuclide metabolism. Animal studies also provide important quantitative and qualitative information about the effects of different exposure conditions and various modifying factors on dose-response relationships. The animal data must be synthesized with available human data to construct predictive models for man. The equation

$$\text{toxicity of Pu in man} = \text{toxicity of Ra in man}\ \frac{\text{toxicity of Pu in dog}}{\text{toxicity of Ra in dog}}$$

is an example of this approach which has guided much of the thinking at the University of Utah project on Pu in dogs. This approach has been amplified and refined in a new theory of bone cancer induction by alpha radiation which has been developed at ANL.

Since no mammal is a sufficient model for man, several species must be used and experimental conditions sought which make possible risk estimates for human populations. By using an interspecies comparative approach, insights are gained into species similarities and differences with respect to sensitivity to hazardous agents, patterns of response, metabolism of internal emitters, and organs at particular risk. The comparison of animal and human data make it possible to determine for any given organ, hazardous agent, or set of exposure conditions which animal species provide the most appropriate model for hazard evaluation in man. Such comparisons are used in developing predictive models applicable to human exposures. Short-lived small animals (rodents) are useful in large-scale experiments designed to obtain statistically valid estimates of risk for low-dose exposures or for studying the influence of exposure conditions or other agents on observed effects. Long-lived large animals are used primarily to study the metabolism of various radionuclides and the pathophysiologic changes associated with diseases which only appear long after exposure.

Full utilization of empirical information will only be accomplished when sufficient understanding of the processes involved in radiation damage exists. It is, therefore, imperative to study changes produced at the organ, cellular, and molecular levels to provide the understanding which will aid in the extrapolation of data from one system to another. Other studies are designed to improve methods for the early detection and diagnosis of abnormalities induced by hazardous agents. These include nuclear medicine techniques which permit lesions to be detected and function to be assessed in single or multiple organ systems. An additional effort of high priority is concerned with developing effective means of protecting exposed individuals against serious injury and with promoting recovery in persons already injured by exposure.

Mechanistic research consists of four different approaches: (1) Studies aimed at understanding the basic nature and normal function of organs and tissues that are uniquely sensitive to ionizing radiation, such as the hematopoietic and immune systems, reproductive cells in the testes, and most epithelial cells that turn over rapidly for normal maintenance of body function; (2) Studies of organ and organ systems that are critical based on the fact that they are the prime target for insult, such as the lung, or because they concentrate hazardous agents or retain them for long periods of time, such as the skeleton, liver, thyroid, and lymph nodes; (3) Studies aimed at developing sensitive indicators of early damage to key organ systems in order to identify effects at earlier times and for ultimate application to man; (4) Studies aimed at the basic understanding of the processes involved in carcinogenic, mutagenic, and teratogenic action of chemical and physical agents.

B. HUMAN HEALTH STUDIES

In order to assess human health risks properly, the magnitude of the dose of a hazardous agent should be quantitatively correlated with the magnitude of the biological effect in man. It is then possible to devise predictive models with which one can calculate estimates of risks or hazards for different levels of human exposure. Predictive models are essential for setting and evaluating human exposure limits, for establishing guidelines with respect to the containment of hazardous agents, and for purposes of making cost/risk/benefit analyses used in long-range energy planning. The development of an adequate predictive capability requires a comprehensive program of research that includes human epidemiological studies, a number of which are currently in progress, to obtain the maximum amount of information on human radiation effects.

Invaluable information on the long-term biological effects of exposure to gamma rays and neutrons in man has come from the ABCC studies on the populations of Hiroshima and Nagasaki. The data collected from this research have provided a major input into all risk estimates for ionizing radiation for

Part III. Detailed Program Description

man that have been made by groups such as the Advisory Committee on the Biological Effects of Ionizing Radiation (BEIR) and ICRP. The ABCC was succeeded by the RERF, an organization jointly and equally funded and administered by the United States and Japan. The Science Council, which functions as a scientific advisory committee to the Board of the Directors of the Foundation has recommended certain changes in the scientific program which will be considered by the Board of Directors.

Study of persons who acquired radium as dial painters, chemists, or medical patients provided the early reference data for the setting of maximum permissible levels for radioisotopes, including that for plutonium. Scientists at the Center for Human Radiobiology, ANL, are continuing and extending the study of human radium cases, and have documented 5000 cases of exposure, 1800 of which have been extensively studied to date. Malignant bone tumors (54 observed) and carcinomas of the mastoid and paranasal sinuses (27 observed) are attributable to the radium deposition. All bone tumors were recorded prior to 1970 while 6 cases of mastoid carcinoma have been reported since then. Theoretical studies of the relative biological effectiveness and of the pattern of deposition in bone of Ra–224 (a short-lived radium isotope) were also accomplished recently.

The Center for Human Radiobiology is also doing a followup study of persons potentially exposed to thorium. Mortality data are being obtained on 5000 former employees of a thorium extraction plant, and a morbidity study, by questionnaire, is planned for a sub-group of 500 men with more than one year of work with thorium. A pilot study of detailed examination, including in-vivo radioactivity measurements,' will be done on 100 men randomly selected from the sub-group. Preliminary work has already shown the presence of measurable amounts of radionuclides of the 232Th decay series in some of the workers.

Studies of the inhabitants of the Marshall Islands exposed to fallout after the March 1, 1954, thermonuclear test have continued under the direction of the Brookhaven National Laboratory (BNL). Currently, Rongelap and Utirik Atolls are visited four times each year by a Brookhaven physician who is stationed at Majuro in the Marshall Islands or by one of Brookhaven's medical teams.

Radiological monitoring is conducted on workers engaged in rehabilitation activities and on inhabitants who have returned to the Atoll. This program is providing valuable scientific information regarding late effects of radionuclide deposition in man due to fallout, particularly thyroid effects due to radioiodine.

An epidemiologic program to study past and current plutonium workers at Hanford, Los Alamos, Mound Laboratories, Oak Ridge, Rocky Flats and Savannah River Plants has been initiated. Data will be accumulated on the incidence of disease in life and the cause of death in present and former employees. A comparison is intended between plutonium workers with detectable plutonium deposition, potentially-exposed workers with no record of detectable plutonium deposition, and plant employees who have not been exposed to plutonium. The first cohort will represent the primary study group and the other two cohorts will serve as comparison groups. Suitable populations for study will be developed at each facility, and uniform methods will be applied at the various facilities so that the resulting data can be pooled for analysis. The total population of workers in the study, including controls, will be approximately 12,000.

The detailed examination of a more limited group of plutonium workers exposed during and subsequent to the Manhattan Project at Los Alamos Scientific Laboratory (LASL), will be continued. The original group of 27 workers has been expanded to 250. A more extensive medical, radiological, and health physics examination is provided to these individuals than is possible in the epidemiologic study described above.

The Transuranium Registry operated by the Hanford Environmental Health Foundation (HEHF), collects and analyzes tissues from autopsies on workers potentially exposed to plutonium in ERDA facilities. Valuable data on the distribution of plutonium in various organs of the body have been developed in the study. In most of the autopsies the highest concentrations were found in the tracheobronchial lymph nodes, lung, and liver. The number of identified transuranium workers as defined by the Registry was doubled during the past year. Permission for whole body autopsies was received and the resulting data should provide improved insight into the distribution of plutonium in the skeletal system.

Radioanalysis of plutonium in tissues obtained from autopsies performed on members of the general population is performed at LASL and Pacific Northwest Laboratory (PNL). At LASL, the autopsy tissues have been obtained from several areas in the U.S., while all tissues analyzed at PNL have been obtained from the Richland, Washington area. This program monitors levels of plutonium in tissues of the general population, both near and at a distance from plants where plutonium is handled.

Cytological evaluation of the sputum of uranium miners is being conducted at St. Mary's Hospital at Grand Junction, Colorado. This includes routine screening and followup of suspected cases of lung cancer. An autopsy registry of uranium miners is maintained and an atlas of sputum cytology is being prepared.

The Radiation Emergency Assistance Center/Training Site (REACTS) facility has been completed and is being operated by the Oak Ridge Associated Universities (ORAU). The REACTS followup program has activated a radiation accident registry for the persons who have received excessive exposures in radiation incidents. In support of this activity an experimental program has been initiated in rats on the pathogenesis of gangrene in extremities as a result of the large local doses of radiation that are sometimes encountered in human exposures. Management of the program of controlling and supplying the chelating agent diethylenetriaminepentaacetic acid (DTPA) to plant physicians for use in the treatment of deposited transuranic nuclides has been delegated by the DBER to REACTS. Courses for physicians in the management of radiation accidents are conducted by the REACTS staff and a guest faculty twice each year. Additional courses of this type will be offered in the future for paramedical personnel of nuclear plants.

The ERDA Health and Mortality Study conducted at the University of Pittsburgh in collaboration with groups at the Oak Ridge, Hanford and Mound Laboratories facilities analyzes the mortality patterns of present and past employees of the Hanford plant. The relationship of levels of exposure to longevity is being explored and will be extended to include exposures from internally deposited radionuclides. At Oak Ridge, collection of data from death certificates of deceased workers and from their current employees will have advanced sufficiently to soon permit analysis of the data on the large population of workers (104,000) and their sibling controls (40,000).

A study at the University of North Carolina of tuberculosis patients exposed to radiation during multiple fluoroscopic examinations for the control of collapse therapy is entering the final phase of data collection with the selection and followup of control groups.

Genetics studies in irradiated human populations are important for the assessment of mutagenic hazards associated with the nuclear energy technologies. Several studies of this type are in progress.

Studies of Japanese populations exposed to radiation from atomic bombs have been extensive but have not revealed clear evidence of genetic damage. It is probable that genetic tests used up to now have not been sensitive enough to detect such damage in humans and more sensitive test systems are being developed. For example, a study was recently begun to determine the extent and nature of chromosomal aberrations in the offspring of radiation-exposed individuals. This study, formerly supported by the ABCC appears promising, and will continue under the newly formed RERF. Another promising new system has been developed which utilizes automated equipment to detect several protein variants with great speed and efficiency. Under the new Foundation, preparations for this study by University of Michigan scientists will be accelerated. Another important aspect of this program is the study of mortality among children born to survivors of radiation.

At the University of Denver, a study continues of the chromosomal aberrations in persons exposed to ^{222}Rn or ^{239}Pu. The number and kind of abberations are compared with the length of time and type of exposure to these radionuclides. This work is important to assess the levels of exposure which induce chromosomal aberrations in proliferating blood cells in humans.

Another newly developed test system can detect somatic mutations or errors in the formation of hemoglobin in blood-forming tissues of certain mammals, including humans. Investgators at ANL and Oak Ridge National Laboratory (ORNL) have collaborated to measure these mutations in blood obtained from a group of Marshallese people. This preliminary study has revealed a greater frequency of mutations in the group exposed to fallout and indicates that this hemoglobin system provides a very sensitive method for quantifying somatic mutations.

C. STUDIES OF RADIATION EFFECTS IN EXPERIMENTAL SYSTEMS

1. Experimental animals

a. External radiation studies

Exposure to external radiation is a potential hazard to occupational groups at various stages of the nuclear fuel cycle; large segments of the general population would not be expected to receive significant exposure. Occupational exposures will most likely involve beta or gamma radiation, neutrons, or mixtures of these radiations.

High exposure levels, i.e., 100 rads or more at high dose rates, produce a variety of pathophysiological effects at relatively short time periods following exposure in sensitive organ systems, many of which show remarkable recovery due primarily to cell replacement. Low exposure levels may produce more subtle effects in exposed individuals only after a long latent period (e.g., cancer or other life shortening effects), damage to the developing embryo or fetus, and genetic damage such as recessive mutations observable in the offspring of exposed individuals. Risk estimates for acute effects following high doses of external radiation are well documented and predictions for man are solidly based on many years of research effort.

Present emphasis in research is based on the urgent need for better quantitative information about the health risks (i.e., mutagenesis, carcinogenesis, and teratogenesis) as very low dose-rates near natural background. These are precisely the conditions which could be encountered in large scale nuclear energy development. Since there is no information available for man under these conditions, statistically reliable data of predictive value attainable within the proper time frame will have to come from carefully controlled experiments with both short- and long-lived animals.

Detection of a significant decrease in life-span shortening at a total radiation dose of 4 rads delivered at a low dose-rate would require exposure of about a million mice and would require 25 years to accomplish even in a very large animal facility. Thus a variety of alternative strategies are presently used to provide the required information. A more reasonable approach is to develop predictive and testable models for dose-effect relationships that can be used for eventual extrapolation to man. Also required are bodies of supportive information that will lead to an understanding of the basic molecular and cellular mechanism(s) involved in the production and expression of the effects and that will "build useful bridges" between experimental animals and man.

Several theoretical models have been advanced which approach a capability of predicting life-shortening or carcinogenic risk at low radiation doses. All of the most advanced theories are based on analysis of information already available, all preclude the need for the multimillion animal sample sizes and all emphasize dose-rate as a more important experimental parameter than total dose for risk estimates from low linear energy transfer radiation. These models are experimentally testable and are being tested at ORNL, ANL, and New York University. At ANL a multispecies analysis will provide the proper scaling factor to be used for short- and long-lived animal species. At ORNL and ANL the influence of radiation quality is being evaluated by comparing the relative biological effectiveness for fission neutrons relative to gamma rays.

The importance of dose-rate can be exemplified by the following findings: (1) Studies utilizing beagle dogs have shown that some diseases that shorten life span are dramatically dose-rate dependent—septicemia and anemia occur at high dose-rates while leukemia occurs at low dose-rates (~5 rads/day). Since all these diseases are due to radiation-induced perturbations in bone marrow differentiation, the differential dependence on dose-rate is remarkable and worthy of increased effort to establish the mechanisms in terms of damage to the hematopoietic system. These studies are now being extended to the study of lower dose rates. The effect of chromic exposure on the developing fetus is also under study; (2) At ORNL it has been found that some types of cancer, notably lung cancer in mice, show a maximum incidence in the range of 5 rads per day. Thus, at least for some types of neoplasia, there appears to be an optimal dose rate at which the highest incidence of tumors will be observed.

All radiation standard setting groups and most risk estimates for man have assumed a linear dose response based only on total radiation dose. The results from the large scale experimental animal studies involving exposures to low linear energy transfer radiations (X- and gamma-rays) are demonstrating that this consistently overestimates the risks for the somatic effects from this type of exposure. While it is still not clear if the dose-response curve for this type of radiation is linear at low dose-rates, it is increasingly apparent that low dose-rates are less effective than high dose-rates in the induction of cancer. Thus the current radiation exposure guidelines for exposure to X- and gamma-rays and beta particles most probably are conservative. It is anticipated that future groups may revise the risk estimates based on the large amount of information developed from the studies in experimental animals.

b. Studies with internally deposited radionuclides

The primary purpose of animal studies with internally deposited radionuclides is to develop a qualitative and quantitative biological basis for assessing the risk to man associated with the exposure to radioactive materials. The research program consists of studies of the metabolism and toxic effects of radionuclides in experimental animals which can be compared with the results of epidemiological and metabolic studies on man. The animal work consists of carefully controlled laboratory experiments in which the metabolism, dosimetry and toxic effects are investigated in a variety of mammalian species with a view to understanding the comparative toxicity and metabolism in sufficient detail to reliably extrapolate to man, using appropriate mathematical modeling suitably tested in experimental animals and man.

The metabolic, dosimetric, and toxic effects studies in animals take into account various routes of exposure (i.e., inhalation, ingestion, intravenous, or intramuscular injection), different physicochemical forms of nuclides, age of the animals, specific metabolic traits of the animals, and the particular suitability of selected animals as models for physiological and pathological processes in humans. The purpose of metabolic studies is to identify the factors influencing localization of radioactive materials in organs, tissues, and cells. The purpose of the dosimetric and toxic effects studies is to understand the types, mechanisms, and degrees of damage in order to assess the biological hazards resulting from incorporation of radionuclides. Collectively, the research program is designed to assess the severity and the nature of the radiobiological lesions from internally deposited radionuclides leading to possible physiological, biochemical, or cytological changes.

To obtain statistically valid data on late somatic effects, life time observations on large groups of animals exposed to graded doses of radionuclides are required. These studies have utilized several species with a range of life spans (primarily rodents and dogs). Since the rodent and the dog are known to exhibit important differences with respect to metabolic patterns and organ function, metabolic studies are in progress on a smaller scale in two other long-lived species, miniature swine and subhuman primates. This comparative multispecies animal approach allows data to be extrapolated to man with greater confidence than would otherwise be possible.

Another major concern, from an occupational and public health standpoint, is the assessment of risks that result from internal exposures to low levels of radiation. The health effects program of ERDA is concerned with accumulating quantitative data on late somatic effects, particularly life shortening and cancer incidence. Since inhalation is expected to be the most common mode of internal deposition of radionuclides in man from nuclear energy operations, exposure of animals via the inhalation route is emphasized. However, in general populations, uptake via the gastrointestinal tract may also be important and work continues with this exposure modality. The response after injection of radionuclides is also studied, since this provides the opportunity to deliver selected doses in well-characterized forms, and to study the comparative metabolism and effects of various radionuclides in several species.

Since it is not possible to conduct comprehensive studies of all radionuclides of interest under a wide variety of conditions, they are studied on a priority basis which depends primarily on the needs established by developing technologies. Those under intensive study now include uranium and the important transuranium elements, principally isotopes of plutonium, americium, and curium; selected fission products, particularly isotopes of strontium, yttrium, cerium, ruthenium, iodine, krypton, and tritium; radium isotopes; and radioisotopes associated with uranium mining, radon, and its radioactive decay products. Studies on the metabolism and effects of high-specific activity uranium isotopes such as in the HTGR and the Light Water Breeder Reactor (LWBR). Studies of inhaled internal emitters are conducted primarily at PNL and at the Inhalation Toxicology Research Institute (ITRI); injected internal emitters are studied at LASL, University of Utah, University of California at Davis, University of California at Berkeley, ANL, PNL, and New York University; ingested internal emitters are studied at PNL, the Comparative Animal Research Laboratory (CARL), and University of California at Davis; incorporation from puncture wounds has been studied at Colorado State University.

The results of animal research (1) provide information required in support of development decisions for various nuclear energy options (both fusion and fission), (2) provide scientific information needed in the process of technology development, review of standards and regulatory aspects, and (3) contribute towards a better scientific and public understanding of health risks associated with the use of nuclear energy.

The information developed from the spectrum of studies on the effects of internally deposited radionuclides in man and experimental animals has been used to establish reasonable exposure guidelines for man. The emphasis of the current research is to provide information for the refinement of these guidelines either upward or downward and to provide positive answers to the significant questions that have been raised relative to the unique dosimetric and toxicity problems from internally deposited radionuclides (e.g., the "hot particle" question).

(1) *Metabolism and effects of alpha-emitting radionuclides*

Knowledge of the health effects resulting from exposure to plutonium is of great importance because of the production of plutonium in current nuclear reactors and because of its projected use as a major nuclear fuel in the fast-breeder reactor. The toxicity of plutonium is markedly influenced by its physicochemical form and route of entry into the body. Previous studies conducted at ANL, PNL, and the University of Utah demonstrated that exposure of rodents and dogs to relatively high doses of plutonium by inhalation or injection results in an increased incidence of tumors in the lung, liver, and bone with the target organ being dependent on the route of exposure and the eventual distribution within the body. The major effort in determining the risk of exposure to plutonium is directed toward an understanding of the factors and events which lead to this tumor formation and toward the identification and quantitation of other effects at doses down to the equivalent of presently accepted limits for occupationally exposed humans. The influence of age and metabolic disturbances on plutonium metabolism and carcinogenicity are also under study at the University of Utah, PNL, and ITRI.

Alpha-emitting aerosols may be classified broadly as being soluble and insoluble. Upon inhalation, insoluble aerosols remain in lung tissue for long periods of time, irradiating cells in the vicinity of the particles. The resulting radiation exposure is very nonuniform and highly variable depending on the number of particles, the size and activity of the particles, and the degree of translocation both on a micro and macro scale within the lung.

There are three major complementary programs designed to assess the degree of risk associated with particles of plutonium dioxide (these are sometimes referred to as "hot particles" if they contain sufficient radioactivity). At ITRI a major series of inhalation exposures of rodents and beagle dogs is underway with uniformly sized (monodisperse) alpha emitting particles. The experimental design includes variability in particle number, size, and specific activity. Although monodisperse aerosols are difficult to generate and rarely occur naturally, these studies should determine the relative risk of pulmonary neoplasia associated with nonuniform vs. uniform distribution of radiation dose to the lung tissue.

A second experiment relating to the hot particle question is being conducted at LASL, in which particles containing plutonim of varying specific activity are deposited in the pulmonary capillaries of Syrian hamsters following injection into the jugular vein. While these exposures differ from inhalation in that translocation to lymph nodes does not occur and the particles remain relatively fixed in location, they do permit precise quantitation of macro- and micro-dosimetry. The carcinogenic response after administration of varying numbers of particles of different sizes and specific activities can then be correlated with differences in dose distribution.

However, since aerosols encountered in nature are varied and polydisperse (i.e., composed of a variety of particle sizes and shapes) it is obligatory to determine the biological effects of such inhaled aerosls. These studies are underway primarily at PNL. Past studies have shown that lung tumors are produced by relatively high lung burdens of inhaled Pu-239 oxide. Similar studies with inhaled Pu-238 indicate that the skeleton may be the tissue at greatest risk for this plutonium isotope as osteosarcomas are produced at a higher incidence than are lung tumors. This difference in critical organ is thought to reflect the greater solubility of the ^{238}Pu. These studies are being extended to lower initial lung burdens which approximate the equivalent of the occupational exposure limits for inhaled plutonium. These studies at ITRI, LASL and PNL are expected to provide information concerning the relative importance of particle size, particle activity, radiation dose and identification of the cells at risk in the induction of lung cancer from inhaled alpha-emitting particlates.

Plutonium nitrate is another major form of plutonium handled by workers involved in nuclear fuel reprocessing. Animals exposed to aerosols of more soluble forms of actinides have shown both lung cancer and osteosarcoma. It is, therefore, uncertain whether lung or bone cancer is the more likely expression of damage in man and what the magnitude of risk may be from low level exposures. Accordingly, low level inhalation exposures of beagle dogs to plutonium nitrate are in progress at PNL and in rodents at PNL and ITRI.

Range-finding studies of the effects in rodents of inhaled oxides and nitrates of plutonium, curium, and americium are in progress at ITRI and PNL. Results from these studies will be used to determine the desirability and necessity for designing detailed studies in large animals (dogs, miniature swine, or primates).

In addition to the prevalence of these radionuclides in the nuclear fuel cycle, the importance of these studies is related directly to a variety of beneficial purposes for which these radioisotopes are used, such as thermoelectric sources (e.g., Pu-238, Cm-244 in heart pacemakers and navigational equipment) and irionization sources (e.g., Am-241 in smoke detectors).

Although chronic or repeated inhalation exposures are considered as possible modes of radionuclide exposure, few data exist concerning the relative hazard of this type of exposure. Therefore, studies on rodents and dogs subjected to repeated exposures to radioactive aerosols were recently initiated at ITRI. Preliminary studies with fission product radionuclides suggest a greater retention of the aerosols in the lung following repeated inhalation exposures than after a single exposure.

The isotopic composition (specific activity) and particle matrix of plutonium produced in nuclear power plants is considerably different from that of "pure" Pu-238, important for space/nuclear power sources, and from that of P-239, important for weapons, which have been used in past studies. Plutonium nuclear reactor fuel may be intimately incorporated with uranium, which will comprise most of the particle mass. In addition, the associated of plutonium containing aerosols with other elements, particularly sodium, might be expected in the LMFBR in the event of an accident, thereby presenting the possibility of a combined risk of inhalation of plutonium and sodium aerosols. Studies at PNL and ITRI are investigating mixed oxides of uranium plutonium, curium, and americium, while mixed sodium—plutonium aerosols are being studied at PNL.

Research on the occupational hazards of aerosols associated with uranium mining continues at PNL, where the toxicity of inhaled radon and its daughter products is being evaluated by inhalation experiments with dogs and rodents. An important feature of this work is that information is being gained on the mechanisms by which exposure to other components of mine air (ore dust, diesel fuel exhaust) and cigarette smoking affect the pulmonary response to inhaled radon daughters.

Although much work on the radiological and toxicological properties of uranium was conducted during and shortly following World War II, little work has been conducted on the higher specific activity isotopes of uranium such as U–233 and U–232 which are used and formed in thorium cycle reactors, such as the HTGR. Accordingly, studies of the disposition and chronic effects of inhaled U–232 and U–233 will be initiates.

The major studies of the effects of alpha-emitting radionuclides deposited in the skeleton are being conducted at the University of Utah. Comparative tumorigenic effects of plutonium, americium, curium, thorium, californium, and radium are being studied after intravenous injection, primarily in the beagle dog. Since there are considerable human data on the induction of bone tumors (osteosarcoma) in radium dial painters, the results of these studies will permit the direct comparison of the effects of radium in the beagle dog at Utah and University of California, Davis, with those observed in humans. The effects of other injected alpha-emitting radionuclides (primarily plutonium and other transuranium elements) in the dog are being compared with those from radium, to provide a basis for the extrapolation of toxicity data from dog to man. Other parameters including the species characteristics, bone dynamics as a function of age, the local bone dosimetry, cells at risk, and the histopathology of induced lesions are being investigated to further strengthen the basis for extrapolation. Studies of the behavior of internal emitters in soft tissues, particularly the liver, are also important, and studies are needed to define translocation rates between tissues. Mathematical models are being refined which relate radiation dose and dose-rate to cancer induction. Studies are now in progress to study the response at doses corresponding to levels equivalent to occupational body burden exposure limits for plutonium in man.

Although the mammalian gut discriminates strongly against most plutonium and transplutonium compounds, there is some absorption, depending upon the chemical form. Previous studies have shown that following gastrointestinal absorption, the skeleton will accumulate the highest radiation dose; accordingly, injection studies are directly relevant to internal distributions in that the ingested material enter the bloodstream. Alphaemiting radionuclides are also incorporated into skeletal tissue following inhalation when they are translocated from the tracheobronchial lymph nodes and lung. The aborption and translocation kinetics of ingested isotopes of plutonium, uranium, neptunium, curium, and californium are being determined in studies at PNL and CARL in order to more accurately predict the amount reaching critical tissues under a variety of physiological and environmental conditions.

The ultimate biologic fate of radionuclides and the effects produced by them are dependent on a number of factors including age, pregnancy, dietary status and drug intake. Studies being performed at CARL and PNL are examining the cross-placental and milk transfer of several radionuclides as well as the influence of age, diet, and other factors on the metabolism and long-term effects of these radionuclides.

At Lawrence Berkeley Laboratory (LBL), the kinetics and distribution of ^{238}Pu, ^{241}Am, and ^{90}Sr at the organ and cellular level are under study in two subhuman primate species, rhesus and cynomologous monkeys. At New York University metabolic studies of ^{241}Am, ^{244}Cm, and ^{210}Pb are underway in another subhuman primate, the baboon, and the kinetics and distribution of these radionuclides are being investigated.

(2) *Metabolism and Effects of Beta-Gamma Emitting Radionuclides*

While alpha-emitting radionuclides are a major area of concern because of their relatively high toxicity compared to beta-gamma-emitting radionuclides, it is essential to recognize that large quantities of beta-gamma-emitting fission product radionuclides are produced in nuclear fission. These radionuclides are separated from plutonium or uranium during fuel reprocessing and then stored as wastes. In addition, certain of these radionuclides such as tritium, krypton, and carbon may be released to the environment under normal operating conditions of the fission fuel cycle. Therefore, the potential health effects of the fission product (beta-gamma) radionuclides must be evaluated.

The comparative metabolism of a variety of fission products in mice, rats, dogs, monkeys, and man is continuing at LASL, including work on alkaline metals such as Cs–137 which is an important radionuclide in fallout and a waste product of all reactor fuel cycles. Studies in a variety of animals of the magnitude and mechanisms of gastrointestinal uptake of Ce–144 are in progress at the CARL to better understand the potential hazard from the ingestion of fission products. At Cornell University studies of the uptake of important fission products in the plant-cow-milk food chain are continuing. However, in the latter studies increasing attention will be devoted to actinides in future years.

A comprehensive program is continuing at ITRI concerning the behavior and biological effects of a number of inhaled beta-gamma radionuclides (primarily fission products), including soluble and insoluble forms of ^{91}Y, ^{90}Y, ^{137}Cs, ^{90}Sr, ^{144}Ce, and ^{106}Ru. Exposure conditions have been used which deliver a wide range of dose rates and total radiation doses to the lung. The emphasis in these studies is to establish the relationships between radiation dose patterns and the resulting biological effects. Results from these studies will be used to compare the effects of low linear energy transfer radiation with those produced by high linear energy transfer radiation from the inhaled alpha emitters being studied at PNL and ITRI.

Current permissible environmental levels for the fission product gas krypton-85 are based on calculations rather than on known biological effects. In order to obtain biological information on the toxicity of inhaled krypton, experimental animal studies with inhaled Kr-85 have been initiated at PNL. In addition, a program at BNL is investigating the metabolism of this radionuclide when very low levels are inhaled by man.

Extensive studies are in progress at the University of California at Davis on the effects of chronically ingested and injected strontium-90 and radium-226 in dogs. These studies are providing an index of estimated risk to humans by correlating the incidence of osteosarcoma and other diseases in the beagle with the same diseases which appeared in radium dial painters. These studies have shown a dose-response to Sr-90 that is apparently non-linear, and they may show a significant dose-rate effect. These and related studies at PNL in which miniature swine (another long-lived species) ingested ^{90}Sr daily will provide a sound basis for the setting of human exposure limits for internally deposited ^{90}Sr. Studies are in progress at PNL in rats, dogs and miniature swine to evaluate the acute lethal hazard for ingested ^{106}Ru in connection with reactor or spent-fuel reprocessing accidents.

Tritium, a heavy radioactive isotope of hydrogen, is produced in fission processes by some neutron interactions with light elements and in fusion of deuterium process by neutron irradiation of lithium. It is expected to be produced in abundance by reactor cycles employing heavy water, and is produced to a lesser extent in other uranium and thorium fuel cycles. At Lawrence Livermore Laboratory (LLL) the effects of tritiated water and external radiation in the mouse and monkey female germ cells and developing fetus are under study. The production of dominant lethal mutations in mice by tritium at exposures equal to 1 to 100 times the present concentration limits in water is under investigation at BNL.

Krypton-85 is another nuclide produced by light water reactors. Studies of its toxicity in rodents are being performed at the Health Effects Research Laboratory of the Environmental Protection Agency (EPA) under an interagency agreement between the ERDA and the EPA.

Studies of radioiodine (^{131}I) effects were originally carried out because of its presence in fallout, but it is an important radionuclide in routine and accidental releases in the nuclear fuel cycle. In addition, ^{129}I is a long-lived fission product potentially released during fuel reprocessing in all fission fuel cycles. Several experimental programs address these problems. At the University of California at Davis, the effects of lifetime exposure to ^{129}I are being investigated in the rat. At the University of Tennessee, a global thyroid collection network is maintained which is useful for studying changes in radioiodine levels with time and the radium contents of thyroids; these studies provide an important bank of tissue for ongoing studies. Other work at the University of Tennessee includes studies of effects of iodine deficiency on reproduction and development in rats and of prevention of accumulation accelerated excretion of iodine from the thyroid. At Case Western Reserve University, physiological and morphological changes in thyroid tissue resulting from ^{131}I administration are studied in rats. When human thyroid tissue becomes available from patients treated with ^{131}I for hypothyroidism, collateral studies of morphology are made. Studies at PNL are comparing the long-term effects, including carcinogenesis of ^{131}I administered to immature rats. At the Cornell Medical Center, studies have shown that administration of stable iodine to iodine-deficient dogs produces cell killing. Expanded studies are contemplated to relate this research to potential lesions in man; if a similar lesion develops in man, this effect may have to be considered in the use of stable iodine to prevent radioiodine accumulation in the event of reactor accidents.

2. Studies of radiation damage in organ, cellular, and molecular systems

Studies of the pathogenesis and biological mechanisms of radiation damage are also essential to the development of radiation protection standards and the development of techniques to alleviate the biological effects. The toxicity studies described in previous sections are providing information on the response to radiation in the intact animal. In order to understand these observed effects and extend the application of knowledge gained from animal experiments, it is essential to understand the basic mechanisms that are responsible for these biological effects.

This type of research is conducted in university-based laboratories and in the following ERDA laboratories: ORNL, BNL, ANL, PNL, ITRI, LLL, LASL, Michigan State University Plant Research Laboratory, and the University of California, Los Angeles.

a. Critical Organ Systems and Pathophysiology

The hematopoietic system is easily perturbed by ionizing radiation and leads to disturbances of production of both white and red blood cells. These disturbances lead to a variety of diseases including septicemia, anemia and leukemia. Studies at LBL, BNL, and ORNL, as well as at a number of university laboratories involve an assessment of the normal function of this system.

The immune system comprises the first line of defense of the body against infectious and malignant diseases and is sensitive to a number of chemical and physical agents. Studies at Franklin McLean Memorial Research Institute (FMMRI) and a number of universities attempt to understand how and when the immune system functions and is perturbed. The role of immunosuppression and/or possible viral activation in the development of radiation-induced tumors is under investigation at PNL, ANL, University of California at Davis and the ITRI. These studies are utilizing animal models of radiation-induced tumors developed from the results of the long-term toxicity studies.

Both the reproductive system and the developing embryo are sensitive to radiation which can induce sterility or a variety of disease states in the offspring. At LLL and two universities, studies of normal development are conducted. Studies at PNL are examining the embryocidal and teratogenic effects of prenatally-administered plutonium, americium and curium.

Pulmonary injury and neoplasia development are well-documented effects of inhaled radionuclides. Studies are in progress at PNL, and ITRI to determine the underlying mechanism of the damage. These include studies on the biochemistry of collagen synthesis in the development of pulmonary fibrosis and studies on the synthesis of pulmonary surfactant in injured and normal lung. The inflammatory response of the lung following radiation injury is being investigated and compared to the response of the lung to other types of injury. The role and function of the pulmonary macrophage in pulmonary clearance and in the pathogenesis of pulmonary disease is also under investigation. In order to understand more about the development of pulmonary neoplasia and the cells at risk from inhaled radionuclides, it is essential that more be known about the kinetics of the pulmonary cells. Studies on the turnover times of lung cells are being initiated.

The skeleton is a site for the eventual deposition of many radionuclides. Studies have shown that the critical cells for the development of bone-related tumors are located on bone surfaces. Thus, the bone surface to volume ratios and the rates of bone remodeling are critical factors for interspecies comparisons.

b. Developing of Improved Bioassay Screening Systems and Early Indicators of Damage

A battery of cytological, biochemical, and physiological indicators of cellular, tissue, and organ damage are under development in the ERDA laboratories. Several of these systems will ultimately provide improved means of detecting and monitoring damage to the human population from exposure to radiation as well as from other agents. At the same time, such tests can provide a realistic method for extrapolating results obtained in experimental animals to normal and susceptible segments of the human population. Promising methods are incorporated into both animal and human research efforts as expeditiously as possible.

New technologies in nuclear medicine research are being exploited to develop the use of radionuclides and new radiopharmaceuticals for the early diagnosis of human diseases. This objective is pursued by supporting research at ERDA laboratories and several university medical laboratories. In addition, the ERDA laboratories conduct cooperative programs both with investigators in the basic sciences and in clinical medical practice.

The nuclear medicine research program develops radionuclide procedures which provide unique diagnostic information for the assessment of organ structure and function. Enhanced organ imaging techniques occupy a major interest in the program. Due to recent advances in instrumentation, there is a growing emphasis on assessment of organ function in general and pulmonary and cardiovascular functions in particular.

A comparative study at FMMRI demonstrated the superiority of nitrogen-13 ammonia over technetium-99m-labeled phosphates to define myocardial infarcts. Research on labeling metabolic compounds with the cyclotron-produced short-lived isotopes is being actively pursued. Use of such compounds will provide data heretofore difficult if not impossible to acquire.

A cooperative study initiated by ORNL with six medical institutions using a common clinical protocol to evaluate potassium-43 in detection of coronary artery disease has just been completed in which over 250 patients were studied. Although the final analysis of the data has not yet been completed, the following preliminary conclusions may be drawn. Changes in the K–43 images were observed in patients where conventional tests failed to detect abnormalities. Also, use of K–43 appeared useful in identifying certain categories of high risk patients that should be excluded from surgical intervention (e.g., by-pass operation). In general, K–43 may be more sensitive than other techniques for detection of single artery disease prior to onset of myocardial damage.

Development of new mehods for measuring lung function are being continued at BNL. An important advance in this area was made by the development of a new class of agents (radioactively-labeled simple amines). These agents localize in the lung and subsequently are metabolized by lung tissue. Administration of these agents not only allows imaging of the lung but provides valuable information on the metabolic integrity of the tissue itself by measuring the rate of release of "$^{14}CO_2$" in the expired air. Combined with more conventional ventilation and perfusion studies, use of these agents will open up new avenues to study lung disease

Comparative assessment of a lung function in a small randomly selected population utilizing dry aerosol techniques, radioactive xenon, and conventional techniques are being conducted at the University of California, Los Angeles. In addition, preclinical studies in heart physiology are being expanded in order to expedite the clinical application of a tomographic scanner for positron emitters. An active program in developing new chemical labeling techniques using short-lived isotopes of various biologically active compounds is also being carried out. One of the products of this program (alcohol labeled with radioactive fluorine) is being assessed as an agent to measure regional brain perfusion.

c. Molecular and cellular studies

The initial action of radiation on cells includes the primary electronic events following initial absorption of radiation energy, the transfer of energy within and between molecules, and the formation of chemical products. Chemical changes in the cellular nucleic acids appear to be the most important, although changes in cell membranes can also be detrimental. Alterations in nucleic acids which comprise the information storage and transfer system can cause permanent genetic damage if not repaired. Interference with the normal information processing system can cause a variety of cellular effects ranging from temporary delays in normal cell growth and division to the formation of aberrant cells to cell death. All aspects are being studied in order to provide the basis for extrapolating these events in mammalian cells to human populations. In addition this work is useful for improving the designs of radioprotective drugs and for synthesizing new chelating agents to remove incorporated radionuclides.

Studies on radiation's initial primary electronic events are being conducted on nucleic acids, proteins, peptides, and other important biomolecules. The development of new and sophisticated instruments are leading to the determination of the actual primary events by permitting measurements of reactions to be made in nanoseconds and by means of low temperature studies. Transfer of energy within and between molecules is being studied to establish the location of energy sinks in biomolecules. An important problem under investigation is the transfer of energy along the polynucleotide chain of DNA to specific bases which may then become centers of high chemical activity. The role of oxygen, free radicals, and reducing compounds as participants in energy transfer processes and modifiers of chemical reactivity are being vigorously pursued. The information gained through these studies provides opportunities for interfering with energy transfer processes in order to prevent cellular damage and to channel the energy into therapeutically useful directions. Also, knowledge about the final chemical products can provide a means for assaying exposure and for establishing the substrates on which repair enzymes must act.

Alterations in cell membranes brought about by radiation are being pursued through studies of radicals generated in biomolecules outside of the cell interacting with the cell membrane. Pulse radiolysis and flash photolysis are being used to study the surface structure of ions and their movement through membranes.

It is now well known that the radiosensitivity of cells varies throughout the cell cycle; most of the projects described below the studies are conducted with respect to the different phases of the cell cycle. These studies include: the action of high and low linear energy transfer radiation; the metabolism of irradiated cells to explore the metabolic derangements that lead to death; and the organization and integrity of the information repository and transfer system.

Studies are underway at ANL, LASL, and the University of Utah to develop an understanding of the chemical binding and subcellular localization of plutonium and other transuranium radionuclides. A better understanding of the kinetics of transport and cellular binding will provide a more rational approach to such factors as interspecies differences in the metabolism of these elements and their eventual removal from the body. It has been shown that the plutonium in the blood is transported by the iron-binding protein, transferring, and studies are being initiated to determine how their protein releases plutonium into the liver and skeleton.

The exposure of cells to ionizing radiation or the intracellular presence of decaying radioisotopes produces DNA damage that may have lethal or mutagenic consequences. Such energy emissions are especially suspect as the cause of single-strand and double-strand breaks in DNA. Radiation-induced free radicals that are labile but hyper-reactive chemically are also generated and contribute to chemical mutagenesis. Ionizing radiation is known to produce damage to pyrimidine- and purine-base components of DNA. Increasing evidence is emerging to suggest that the various types of radiation damage are reversible by enzymatic repair mechanisms. Thus far, repair mechanisms can be classified within three groups: (1) those which specifically reverse a particular chemical change in DNA, (2) those which remove the damaged sequence, or (3) those in which the damaged DNA strand is entirely replaced in the process of DNA replication. Recent results have indicated some degree of DNA repair from high linear energy transfer radiation.

Mechanisms that correct molecular damage to DNA utilize enzymes whose formation is controlled by chromosomal genes. Deficient mutations in genes that code for repair enzymes create increased susceptibility to the particular variety of DNA damage that is ordinarily corrected by that repair system. Such vulnerability may culminate in early onset of cancer, aging, and other disease syndromes in man. The characterization of radiation-sensitive mutants is a powerful genetic approach that is currently being exploited in a wide spectrum of experimental systems. Increased susceptibility of various mutants to irradiation implicates the roles of the deficient genes in the repair process, especially after confirmation in vitro of a particular enzyme defect.

The enzymes that are involved in DNA repair catalyze reactions which are also involved in such processes as DNA replication or DNA recombination. In fact, there is evidence that some of these enzymes may have multiple, overlapping functions. Therefore, alterations in repair enzymes as the result of mutations may simultaneously alter other cellular functions. Considerable emphasis is being given to the sorting out of a large number of complex gene-enzyme relationships, taking into account the heterogeneous array of different repair systems as well as the possible multi-functional roles of repair systems in other DNA processes. Such gene-enzyme relationships can now be studied in human cells cultured in vitro, and this approach is being emphasized at ORNL and BNL. The understanding of the particular action of each DNA-damaging agent and its cognate repair mechanism is necessary in order to assess the possible synergistic effects of combined exposure to mutagenic agents.

3. Genetic studies

The program in radiation genetics is designed to define the level of genetic damage that would result from subjecting human populations to radiation exposure. Somatic mutations and their significance are also being assessed. Damage to the genetic material can be detected and measured as specific endpoints such as an increased rate of mutation of individual genes, or of induction of various kinds of chromosomal aberrations, etc. These are the endpoints that are detectable and measurable in the laboratory and are usually studies in experimental organisms, although on occasion valuable observations can also be made on human populations that have been exposed to radiation.

Because of the limited availability of exposed human populations, the limitations on the procedures that are possible and permissible with human subjects, and the limited number of humans exposed to significant doses of radiation available for investigation, the studies on irradiated humans are primarily confirmatory in nature, and by themselves cannot supply an adequate basis for making risk estimates for the genetic effects of radiation. Even when human studies can be made, experiments with animals, and with cellular and molecular systems must supply the understanding of genetics events needed for interpretation, as well as much of the methodology.

The information that is needed in making estimates of human damage must come from studies in a variety of organisms, each chosen for its suitability in the answering of specific questions related to mutagenesis and its consequence. The questions that must be answered are: (1) What is the sensitivity of the human germ plasm and how can we estimate the rate of radiation-induced mutations? For example, what kind of numerical relationship would hold between mutation in mice and in humans? (2) Given an accurate estimate of the amount of damage to the human germ plasm, what does it mean in terms of an added burden of genetic disease and disability? Studies must be directed at mutation processes and the nature of the mutation condition as well as at population processes, at mechanisms in the production of aberrant individuals, and the mechanism by which defective genes are eliminated from the population.

The major kinds of genetic damage are effects on single genes ("point mutation"), and effects on chromosomes (chromosome aberrations), the latter being of two kinds, rearrangements of chromosomes that may affect the transmission of complete sets of genes to offspring, and numerical aberrations, where the chromosomes may be structurally intact, but the wrong numbers of chromosomes are transmitted. Each of these can contribute to serious development defects.

a. Studies with external radiation

Currently, genetic risks estimates of radiation-induced increases in point mutations are based on three kinds of considerations: (1) the rate of induced mutation relative to the spontaneous rate, (2) the incidence of human genetic disease, and its dependence on recurrent mutation, and (3) estimates of how changes in mutation rate will, through changing gene frequencies in the population, alter the incidence of various kinds of human disease. Evaluation of (1) and (3) currently cannot be made with data available from humans, and recent surveys of human populations have given radically different pictures of item (2), and the incidence of human genetic disease.

(*1*) *Measurement and estimation of gene mutation rates*

The raw data on induced mutation rates that are currently most used for the genetic risk of radiation to man are those derived from mouse studies that were conducted for more than two decades at ORNL. These studies have played a key role in evaluating the genetic hazards of radiation for humans and have been used in setting the standards for radiation exposure. These studies have shown a marked difference in sensitivities of germ cells of the two sexes, and have shown further that there is a markedly lower rate of damage when the exposure is protracted that when given in a short time interval.

Studies on human radiation-induced genetic mutations have in the past been limited to studies on early mortality of the offspring of the Japanese survivors of radiation released by atomic bombs. These studies are now being expanded to include investigation of rare protein variants in hemoglobin in the Japanese survivors. It is not yet certain that these studies will permit precise estimation of the human radiation-induced mutation rate, or even what fraction of the total mutational spectrum will be represented in these studies. They will be useful, however, in making comparisons with other organisms and should permit greater confidence in making human risk estimates.

Since it is necessary to base refinements in genetic risks estimates to man on information from sources other than human germ cells, it is essential to recognize the limitations of the methods used. Cells in different stages of development may differ greatly in radiosensitivity, and marked differences between species are also found. In order to extrapolate from the effects observed in lower organisms to the potential effects in man, it is necessary to develop methods of making meaningful comparisons. Empirical comparisons, using a wide variety of organisms should define a range of sensitivities that should include human radiation sensitivity. However, confidence will be improved as we learn more about the nature of the molecular events involved in radiation damage and its repair.

Mutation studies in viruses and in bacteria (prokaryotes) have given invaluable insight into the nature of mutation, the nature of gene action and its control. However, genes in higher organisms (eukaryotes) have a more complex organization and are involved in development regulations in ways that are not shared with the prokaryotes. Understanding the consequences of mutation in a eukaryote, such as the human, requires understanding of genetic organization in eukaryotes. The effects of interfering in normal gene action can be understood only if we know how gene action is evoked and represses, and how these processes may be altered by mutation. Therefore, research on the genetic organization and the analysis of mutant genes in eukaryotes has a high priority.

The culturing of somatic cells of mammalian species, including those of man, appears to be a promising way of making some of the comparisons, since it will make possible a variety of procedures that can be carried out relatively rapidly. The development of procedures for screening for mutants and for the genetic analysis of the mutations that occur has high priority.

(*2*) *Mutant genes in population*

The effect of an increase in mutation rate in germ cells is to increase the frequencies of less desirable genes in the population. The consequences of this would be some increase in the incidence of genetic disease and other inherited handicapping conditions in the population. Precise estimation of the change in incidence of disease requires detailed knowledge of the populational processes that take place, particularly what it is that maintains the current incidence of genetic disease. The process of elimination of mutant genes from natural populations is being studied by several investigators.

These problems are relatively simple in the case of mutant genes whose effects can be seen singly, but become complex in conditions that are brought about by substitutions at a number of genetic loci (polygenic or multifactorial characters). Most of the human disease with which we are concerned falls in this category. The assessment of the impact of mutation on the incidence of hereditary diseases of a more complex nature (e.g., diabetes) requires that there first be a better development of the concepts of how the normal genetic variability that underlies the variable expression of polygenic characters is maintained in natural populations. These studies need to be pursued at theoretical and experimental levels to furnish a better basis for understanding genetic studies on normal human populations, which in turn are needed to understand the effects of altering the mutation rate.

Studies are made on human populations wherever appropriate populations can be found. These must be populations that are well defined in terms of composition (minimal migration), and where record keeping makes it possible to link the various records that will enable investigators to make correlations useful in interpreting genetic effects. The purpose of these studies is to supply a basis for evaluating effects, rather than to supply directly a measure of the effects of increased mutation. These studies supply information for one of the key steps in estimating the consequences of increased mutation and therefore are given high priority.

(3) *Chromosomal Aberrations*

Work on chromosome aberrations involves a variety of organisms, including humans that have been exposed to significant radiation doses. Evaluation of cytogenetic damage in human populations requires the ability to estimate levels of damage at low doses and the ability to describe the consequences of aberration as these affect the normal distribution of genetic material to the functional germ cells. Work with mammalian species will show how these respond, quantitatively, and will serve to verify that the mechanical problems of genetic transmission are not different from those in organisms where more sophisticated genetic analysis is possible. Finally, wherever it is possible to study these processes in exposed humans, it is imperative to do so in order to verify the nature and level of human response to radiation.

In evaluating cytogenetic endpoints, there is a need for an understanding of the normal mechanisms of genetic transmission. The proper analysis of these processes must first be carried out in lower organisms, since it is only with a limited number of these that adequate methodology exists. Whenever possible, confirmatory studies should be made using mammalism species.

Chromosomal aberrations constitute a major class of human genetic disability. Aberrations of concern involve either rearrangements of segments of chromosomes (structural aberration) or changes in the number of chromosomes without significant change in their individual genetic content (numerical aberration). The genetic effect of the latter is abnormal development of individuals having the wrong number of chromosomes. The adverse genetic effects of structural aberrations are due mainly to the production of individuals of unbalanced chromosomal constitution in subsequent generations. The effect of imbalance, in either case, is abnormal development. In the majority of cases, this results in fetal death at relatively early stages of development. The consequences of chromosomal imbalance, in some cases, may be relatively trivial.

The kinds of information that are still needed in evaluating the consequences of chromosome damage include knowing how the different classes of structural aberration, primarily reciprocal translocation and Robertsonian translocation, are formed, relative to the germ cell stages at risk. The risk of Robertsonian transformation seems very low for male germ cells, but there is strong reason to believe that the conditions in the female germ cells (primary oocytes) may favor this kind of aberrations. This will require additional work with mammals, preferably with a species other than the mouse. The nature of the mechanisms of induction of numerical aberrations in an experimental insect (Drosophila) is known, but needs confirmation in mammals.

There appears to be a difference in the nature of the dose response for aberration induction between mammals and lower organisms that have been used to elucidate mechanisms. It is not known if this difference in response is due to some real biological difference, or is an artifact produced by comparing results in experiments where sampling methods are imprecise with those from experiments with precise sampling. Evaluation of low dose effects requires an answer to this question.

It is known that some kinds of rearrangements are not transmissible through the male, due to sterility. A more thorough analysis of the nature of such non-transmissible rearrangements is needed. More information is needed to relate the process of induction to the nature of the cell at risk in order to estimate the fraction of translocations induced in humans that would be non-transmissible.

(4) *Chromosome studies in human populations*

Observations are being made on the offspring of the atomic bomb survivors in Japan, to determine the aberrations that are detectable by current cytogenetic methods. These studies can be used in conjunction with studies in other organisms to verify the range of sensitivity of human germ plasm to cytogenetic radiation damage. In other studies chromosome damage in somatic cells of exposed humans is being examined. These kinds of studies will lead to an improved evaluation of the effects of germ cells in humans, through comparisons of germ cell and somatic cell effects.

Only limited observations have been made on normal human populations, where cytogenetic endpoints have been scored. More information is needed from systematic population surveys. Prospective surveys of pregnancies in a normal population are needed with diligent cytogenetic evaluation of all products, liveborn as well as aborted fetuses.

The collection of information from such surveys, to establish the level of cytogenetic defects in normal human populations and the consequences of these, will be greatly advanced by methods of applying pattern recognition techniques to human chromosome preparations. Continued support of efforts to develop and improve these techniques was high priority.

While it is well documented that radiation induces genetic changes in somatic as well as germ cells, the significance of these in somatic cells is largely unknown. The use of cultured lymphocytes from peripheral blood has been developed to provide an integrated biological estimate of radiation dose received from whole or partial body irradiation.

b. Studies with internally deposited radionuclides

Because of the greater precision of dosimetry, much of the work on genetic effects of radiation has employed external sources. Most of this work, especially on the mechanisms of mutation, is also directly applicable to radiation from internally deposited radionuclides. Research on the genetic effect of internally deposited radionuclides has been limited to those cases where specific questions relate to the properties of the radionuclide and/or the effects of its incorporation into the genetic material, or the effects of some specific radionuclide that may constitute a special occupational or environmental hazard.

For genetic effects, it is necessary to determine if a radionuclide incorporated into the genetic material produces mutation by its emitted radiation (e.g., beta radiation from tritium) or by its transmutation into another element. Work of this kind in bacteria has been supported in the past and currently is being supported in studies with higher organisms. Studies are being carried out in the mouse to evaluate the relative biological effectiveness of tritium beta radiation on mutation. Since tritium is a potential source of human radiation exposure, this work will provide a better basis for estimating human damage from the random incorporation of tritium in the body including that incorporated in the DNA. Studies at ORNL, LLL, and BNL are concerned with the genetic effects in mice of low exposures to tritium. Tritium is receiving emphasis due to its abundance and potential for release in all phases of the nuclear fuel cycle and in proposed fusion reactors.

While the deposition of plutonium and transplutonium elements in the gonads of mammals is very low (less than .1% of that in the blood) there is concern for the potential genetic effects of this deposition due to the densely ionizing alpha particle emissions of these radionuclides. Studies to delineate the genetic effects if any of plutonium have recently been initiated at ANL. This study is designed to determine uptake and retention coefficients for plutonium in the gonads and to determine the microdistribution of the dose within the gonad as well as the assessment of genetic damage by determining dominant lethal mutation rates and chromosomal aberrations. A new study at ORNL will use the specific locus method to further assess the potential genetic effects of plutonium.

At ITRI studies on the relative biological effectiveness of various types of radiation from either external sources or internally-deposited, liver-seeking radionuclides including transuranic elements, for the production of chromosomal aberrations in regenerating liver cells are in progress. Also included is the determination of the relative effectiveness of a uniformly and non-uniformly distributed dose. Also at ITRI, rhesus monkeys exposed to aerosols of $^{239}PuO_2$ are being studied to determine rates of chromosomal aberration in cultured lymphocytes at various times post-inhalation and over a wide range of lung burdens. This study relates to the reported increase in chromosome aberrations in lymposcytes of humans who accidentally inhaled plutonium from occupational exposures. However, the history of the workers regarding external radiation exposure complicates the interpretation of the cause of their chromosomal aberrations.

D. RECOVERY AND TREATMENT

Research is being conducted to develop effective safe methods of preventing or reducing the toxic effects of ionizing radiation in man. Research is directed toward the evaluation of therapeutic procedures including; (1) the administration of radioprotective drugs that activate molecular species produced by ionizing radiation in living tissues, and (2) the use of special agents or procedures that accelerate excretion or decrease absorption and reduce the risk associated with plutonium or other radionuclides deposited internally. Studies at ORNL are aimed at determining tissue levels of a phosphorothioate radioprotective compound (WR–2721) in normal and tumor-bearing animals of several rodent species. Preliminary data indicate that this compound is not readily absorbed by most solid tumors and that it selectively protects normal tissue in tumor-bearing mice. Research at the University of California at San Francisco is assessing the radioprotective properties of this compound in larger animal species. Both studies suggest that WR–2721 may prove useful as an adjunct in radiotherapy of cancer. Work at PNL has demonstrated that WR–2721 affords substantial protection to the gastrointestinal tract of mice exposed to high levels (1500R) of X-irradiation.

The currently accepted treatment for plutonium and many other radionuclides deposited in the body consists of chelation therapy possibly combined with early bronchopulmonary lavage if the radionuclide was inhaled. Past studies have shown that the chelating agent DTPA readily binds to plutonium and related radionuclides in the blood to form soluble complexes that are eliminated via the kidneys. The calcium salt of DTPA is approved for investigational use in humans and is used to treat accidental exposures of man. However, the calcium salt has been shown to be severely embryotoxic in mice and rats although at doses far above those used in clinical practice. Studies at PNL and the University of Utah have demonstrated that the zinc salt of DTPA, which is as effective as the calcium salt, is less toxic, and can be chronically administered safely over prolonged time periods. Thus, research is now in progress to develop the most effective therapeutic regimes for zinc DTPA and develop the necessary toxicity information relative to its possible use for therapy in man.

While the current therapeutic regimes utilizing DTPA removes a variable percentage of the internally deposited radionuclide, its efficacy in removing plutonium and other radionuclides deposited in bone and liver is limited. Several approaches to overcome this limitation are being investigated. The first of these is the synthesis of new chelating agents with a higher degree of specificity and/or a greater solubility in lipids. Studies at the University of Utah are investigating the efficacy and toxicity of multi-heteromacrocyclic molecules synthesized at the University of California at Los Angeles. These compounds can shape themselves to the actinide ion to provide a very high level of specificity of chelation. Another approach developed at ANL is the investigation of the efficacy of DTPA encapsulated into lipid materials prior to their administration to increase the entry of DTPA into the cell. Still another approach is to develop repository forms of zinc DTPA to provide chronic or continuous chelation therapy. Investigation of a technique has now begun at the University of Pittsburgh in which mixed ligand chelates will be administered separately, and are expected to bind plutonium in such a way as to permit passage across membranes. The administration of two separate compounds will be required as opposed to the classical approach of administration of a single agent. Screening techniques to test a large variety of compounds will be undertaken in vitro and the promising compounds tested in vivo in rodents.

Studies at New York University have shown that calcium DTPA is more effective in removing Am-241 deposited in the skeleton from the juvenile baboon as compared with the adult. Similar therapy in a human juvenile was surprisingly effective in reducing skeletal and liver depositions of Am-241 acquired several years ago in an accident.

As inflation is the most prevalent mode of exposure in accidents with nuclear materials and standard chelation therapy is relatively ineffective in removing inhaled materials, particularly if they are relatively insoluble, efficient therapy for inhalation deposition is needed. Bronchopulmonary lavage therapy which consists of flushing or washing the lung with physiological saline solution has been systematically evaluated in beagle dogs at ITRI. Both the efficacy of the removal of the inhaled radionuclide and the safety of the technique are being evaluated. With current methods the technique is effective in removing about 40 percent of the inhaled material. Methods to increase the efficacy of removal and to understand the factors responsible for variations in efficacy are underway. The successful development of this technique in dogs has led to the application of the technique to treat one case of an accidental inhalation exposure to plutonium in a man. Also, some of the techniques developed in dogs have led to the adaptation of a single lumen lavage technique for the successful lavage of infant humans for alleviation of the symptoms of cystic fibrosis and other pulmonary diseases. The efficacy of DTPA administered by inhalation rather than injection is being investigated at PNL.

In addition to evaluating the efficacy of therapeutic techniques in removing deposited radionuclides, studies are underway at PNL and ITRI to evaluate the efficacy of these therapeutic techniques in reducing the incidence and severity of biological effects. It is essential to recognize that the reduction in the body burden by therapeutic techniques may or may not proportionately reduce the biological consequences. Thus, animals treated by chelation therapy and bronchopulmonary lavage are being observed to determine the efficacy of these techniques in reducing the biological effects.

Part IV. Summary and Recommendations for Future Research

The important nuclear technologies are (1) Non-Breeding Fission Reactors utilizing the uranium fuel cycle, (2) High Temperature Gas-Colled Reactors which utilize the thorium fuel cycle to produce fissionable high specific activity uranium, (3) the Light Water Self-Sustaining Reactors which utilize the thorium fuel cycle, (4) the Liquid Metal Fast Breeder Reactor and possibly other types of breeder reactors which produce large amounts of plutonium, and (5) Fusion Power Systems as Controlled Thermonuclear Reactors as well as Laser Fusion Reactors.

Each of the converter and breeder reactor systems requires mining of uranium or thorium ores, extraction of fissionable material from these ores, fabrication of fuel elements, the use of this fuel in nuclear power reactors, the reprocessing of fuel, transportation, and ultimate disposal of radioactive waste. Each stage of the fuel cycle presents potential hazards to occupational population groups and potential hazards to the general population from the low-level routine releases, or from accidents which may occur at particular stages of the nuclear fuel cycle.

The major health hazards to man from present or future nuclear technologies are those involving radiation exposure either from external sources or from radioactive materials (radionuclides) deposited internally. These radioactive materials are primarily the large amounts of fissionable materials that are utilized by or recovered from both non-breeding and breeding types of reactors, fission products, and activation products of fuel or structural materials used in both fission and fusion reactors.

While our understanding of the short-term effects of high doses of radiation from these materials is adequate, a major gap in our knowledge is the long-term consequence of acute and chronic exposure to low levels of radiation.

Future nuclear technologies (e.g., breeder reactors) will both use and generate large quantities of toxic actinide elements (plutonium, americium, curium, etc.) that emit densely ionizing radiation for which the health consequences are not adequately defined, but which might include lung cancer, bone cancer, and possibly liver cancer. Growth in application of current and future nuclear technologies is critically dependent on obtaining reliable quantitative information on the health effects of these radionuclides, whether internally deposited (alpha and beta emitters) or causing external exposure from their penetrating emissions (beta-gamma emitters). Neutron and gamma exposures are potential hazards in the immediate proximity to operating reactors. The following objectives outline the scope of the current and future health related research necessary for the development of these technologies:

Objective I.—Identify and measure the spectrum of radioactive and non-radioactive pollutants associated with the uranium and thorium fuel cycles. This is composed of three research areas.

1. Identify and measure the spectrum of particulate and gaseous aerosols associated with work cycles and ore-handling operations in uranium and thorium mining.
2. Identify and measure the gaseous, liquid, and particulate effluents from milling and other processes involved in uranium, thorium and plutonium extraction, separation, processing, and waste storage.
3. Identify and measure the radioactive and non-radioactive agents in mine tailings that are hazardous and may cause human exposure.

Large scale use of non-breeding, electric-power producing reactors will require greatly increased mining and milling of uranium ores. It is expected that future ore reserves will come from deeper mines with increased potential for exposure of workers to radon, radon daughters, and a variety of gaseous organic and inorganic pollutants from mining machinery. Interaction of radioactive and non-radioactive pollutants can increase the human risk to debilitating respiratory diseases as well as to lung cancer. It will be necessary to identify the spectrum of radioactive materials associated with the mining and milling operations as well as to monitor those materials as a routine part of the operations. It will also be necessary to identify and measure the radioactive gaseous, liquid, and solid particulate agents involved in the fuel extraction, fabrication, reprocessing, and waste storages of the fuel cycle.

Objective II.—Determine the metabolism and biological fate of alpha-emitting actinide elements and of the specific fission and activation products associated with advanced nuclear technology. This involves five project areas.

1. Determine the mechanism and kinetics of incorporation, metabolism, deposition, and turnover of the actinide elements (uranium plutonium, curium, americium) in the various chemical forms encountered in the nuclear fuel cycles in human and experimental animal populations.
2. Determine the mechanisms and kinetics of deposition and turnover of fission and activation-roduct radionuclides.
3. Determine the influence of age, sex, metabolic, state, diet, prior disease, other internal contaminants, and other physiologic factors on the metabolic behavior of relevant radionuclides.
4. Determine the metabolism of the actinide elements for conditions of low level continuous exposure.
5. Determine the metabolism of mixtures of actinides that will commonly be encountered in the nuclear fuel cycle.

The ultimate evaluation of health risk must be in terms of the absorbed radiation dose which often differs markedly from the exposure dose. This information must be derived from detailed measurement and understanding of the mechanisms and kinetics of the incorporation of inhaled, ingested, or injected radioactive materials as well as the translocation, deposition, turnover, and excretion of actinide elements as well as fission and activation products to which man might be exposed.

Emphasis will continue to be placed on the biological behavior of radionuclides following inhalation. Since exposure to radioactive hazardous pollutants can be indirect via water to soil to man's food chain, it is important to evaluate this route of transport to man and to determine the hazards of ingested radionuclides. Inhaled radionuclides cleared from the lungs may also be absorbed from the gastrointestinal tract.

Metabolic data will be obtained from human exposure cases where possible but most of the information will be derived from comparative studies using model experimental animals. Such metabolic data are needed to accurately compute the absorbed dose, which when evaluated with effects permit reliable predictions of risk to people.

Objective III.—Evaluate the short- and long-term carcinogenic, pathophysiological, teratogenic, and mutagenic hazards of the fuel cycle elements in formal, susceptible, and stressed populations. This involves three major program areas.

1. Conduct epidemiological and clinical studies in selected human population groups to evaluate the long-term hazards of exposure to radiation both from external sources and from internally deposited radionuclides.

2. Correlate the long- and short-term effects of the various actinide elements with the deposition levels in specific organs in exposed human and animal populations.

3. Correlate the long- and short-term effects of the various fission and activation products with the deposition levels in specific organs in exposed human and animal populations.

The major health hazards associated with the nuclear fuel cycles will be latent pathophysiological effects which produce debilitating respiratory and systemic organ disease as well as carcinogenic, mutagenic, and teratogenic effects. Although evaluation of these effects at relatively high exposure levels is quite advanced, much more information is needed to provide reliable quantitative estimates of the health risks from low level continuous exposure to the actinide elements such as plutonium, americium curium, and the higher actinide series produced in advanced non-breeder reactors. In addition, much more information is required to assess the synergistic action of radioactive and non-radioactive pollutants in production of pathophysiological damage as well as carcinogenic, teratogenic, and mutagenic effects in the occupational or general population.

Because the degree of exposure to man has not often been much less than exposure levels where biological effects have been observed in experimental animals, it is necessary to extrapolate from higher dose experiments in animals to lower dose experience in man. There is inadequate information in this area.

There is very little information on the biological effect of chronic exposure to actinides. Most of the previous experimental work related to late effects used single exposures while the late effects associated with human population will be of chronic nature. Experimental data using animal models are urgently needed and studies of this nature have recently been initiated.

Objective IV.— Determine the processes of damage, repair, recovery, protection, and amelioration in biological systems exposed to hazardous agents associated with nuclear technologies. This is composed of four research areas.

1. Identify the mechanisms by which living systems repair and recover from lesions induced by exposure to radiation, and assess the role of the mechanisms in human recovery from exposure to radiation.

2. Identify the biochemical lesions induced by interaction of biological systems with radiation in order to identify susceptible population groups, provide early indicators of injury, and guide the development of protective and remedial therapies.

3. Develop and test methods to enhance normal recovery and repair mechanisms, and develop protective remedial therapies.

4. Develop and test devices and procedures to protect against the effects of radiation, particularly in the occupational setting.

The information developed under Objective II will be used in the development of remedial methods to reduce or remove internally deposited redionuclides arising from nuclear technologies; when developed, these same techniques may also provide safe decorporation therapy for nonradioactive heavy metal poisoning (cadmium, mercury, lead).

Objective V.—Determine the Future Health Hazards Associated with Fusion Reactors.

The major potential health problems currently envisioned for most of the fusion technologies revolve around tritium, neutron activation products and magnetic fields. If the hybrid fusion-fission concept is employed, the actinide elements could be of concern.

The tritium involved in fusion reactors will be present as the gas and the amount will be large. Although there is large literature on the biological effects of tritium as tritiated water, additional information is needed on the effects of tritium gas.

The actual activation products which will be produced will depend on the structural materials ultimately used. Although these have not been fully defined, it is expected that aluminum, boron, niobium, stainless steel, titanium and vanadium are likely to be important constituents.

The use of large magnetic fields represents an area unique to fusion reactors. Although there is a large body of literature on the biological effects of magnetic fields, the quality of the information is inadequate to guide the setting of standards. Therefore, a program is being initiated to investigate the biological effects of magnetic fields under a wide-spectrum of conditions.

It will be necessary to periodically evaluate the potential health effects associated with fusion systems. The Laser/Fusion Safety Committee which has been established within ERDA is expected to contribute to the identification of possible problems so that the health effects studies can keep pace with the development of the technology.

SUMMARY

The research effort on the potential health effects of current and projected nuclear technologies has increased significantly over the past 10 years. Most recently the potential health effects of transuranic radionuclides have been given greatest emphasis. The status of the current research is continuously evaluated and problems emerging from developing technologies are included as soon as possible. Several review groups assist BER staff in directing the emphasis of the research. Research has been initiated to adequately answer the objections I–V outlined previously. Although much of the research has been initiated over the past 5 years, certain critical problem areas such as mixed oxides, plutonium and sodium aerosols, plutonium nitrate, and chronic exposures are just now being addressed. Work on combined insults such as plutonium inhalation and another pulmonary insult (i.e, cigarette smoking) is in very early stages of investigation.

Many of the low dose level studies that have been initiated will require several years to complete. It is also certain that, as they are identified, other needs will be given high priority as alternate reactor systems emerge. Thus, while it is anticipated that funding for research on the health effects of nuclear technology will not increase markedly, funding of projects to provide the answers to the stated objectives will be continued.

NON-IONIZING RADIATION*

ENVIRONMENTAL STUDIES

NUCLEAR RELATED RESEARCH

Nuclear related research has undergone reprogramming and redirection over the last two years which has led to changes in emphasis but no diminution in the overall program. In general, research on the transport and fate of intermediate-lived fission products has been curtailed as a large data base exists. Similar reductions in chronic irradiation experiments have occurred as major objectives have been met. Concurrently, however, increasing emphasis has been placed upon the environmental behavior of the transuranium elements, the radioecology of uranium, certain very long-lived fission products and radionuclides associated with controlled thermonuclear reactors.

Two programs formerly classified as nuclear have been reclassified as multitechnology. These involve ecological effect of cooling systems (thermal) and research related to offshore power plant siting.

ENVIRONMENTAL STUDIES OF PLUTONIUM AND OTHER TRANSURANIC ELEMENTS

In fiscal year 1974, the BER program in environmental research for the transuranium elements consisted of land, freshwater and marine research on the biogeochemistry of plutonium, plant uptake of plutonium and americium under greenhouse conditions and limited ecosystem transport.

In fiscal year 1975, major aquatic and terrestrial ecosystem studies were begun at locations known to have been contaminated above fallout background levels. Food chain studies related to pathways to man were expanded to include field studies of plant uptake under agricultural conditions and ruminant feeding studies to evaluate milk and meat contamination. Soil chemistry, plant uptake, and ruminant feeding studies with curium and neptunium were also started. An ongoing study in the Marshall Islands in marine sciences has been supplemented by land and freshwater investigations to determine the fate of transuranium elements in Enewetok Atoll.

In fiscal year 1976, support was increased for all of the foregoing areas, and additional work was begun to develop information on the long-term behavior of the transuranium elements in the environment. Three approaches are underway:

(1) The identification of soil and sediment chemistry parameters which affect the mobilization of the transuranium elements.

(2) Long-term agricultural experiments to determine effects of weathering and aging upon availability of these elements.

(3) Study of the behavior and availability of certain elements which have analogous chemical properties to transuranium elements and which have been undergoing weathering and aging in soils through geologic time.

In fiscal year 1977, the program elements have continued with increases in analytical support to some programs and the completion of two projects.

RADIATION EFFECTS OF CHRONIC EXPOSURES ON ECOSYSTEMS AND OTHER STUDIES

While the transuranium research was expanding, some of the support for older nuclear research areas was being reduced. Chronic radiation studies of ecosystem were reduced to maintenance levels as the major objectives of that program were met. Studies involving fission products with short and intermediate half lives were curtailed except where major questions still need to be answered (e.g., persistence of ^{137}Cs availability to food chains in the Southeastern U.S., ^{55}Fe inputs to marine systems and their subsequent transfer through the marine food webs). High altitude sampling programs for weapons debris and development of the Atmospheric Release Advisory Committee (ARAC) have maintained essentially level funding in atmospheric sciences.

New programs dealing with certain fission products have expanded over this same period of time. The long-lived ^{129}I and ^{99}Tc are presently under investigation in laboratory and field studies. The absorption and bioaccumulation of tritium gas in soils and plants and the transport of triliated water from rivers to estuaries and across the continental shelf are other areas which are receiving attention. New programs were initiated in fiscal year 1976 on the radioecology of the higher specific activity species of uranium, and on the ecological aspects of uranium tailings and their stabilization.

NUCLEAR ORIENTED RESEARCH ACTIVITIES WITHIN THE PHYSICAL AND TECHNOLOGICAL PROGRAM

The nuclear related research activities within the Physical and Technological Program addresses five major research areas. These research categories are outlined below with a brief description of the program content.

Radiological physics research.—This research is concerned with determining the physical parameters that govern radiation interaction within biological systems. This information is required so that theories or models which describe and predict radiation effects can be formulated. Although our physical understanding of radiation interaction is far from complete, knowledge is sufficient to permit an aggressive effort to develop descriptive theories of radiation action. Consequently, the radiological physics research program is decreasing to permit an expansion in the development of theories of radiobiological action.

Development of theories of radiobiological action.—Physical parameters such as molecular excitation, free radical formation, and their spatial and temporal distribution serve as the foundation upon which models of biological effects are developed. The results of these studies have recently impacted two important areas. Analysis of biological effects at low exposures for high LET radiation is providing a new insight into low-dose radiation effects. The second area in which these studies are finding application involves the planned use of new radiation beams (heavy ions and negative pi mesons) for radiation therapy. The theories are important in estimating the effectiveness of various beam configuration and treatment plans.

Neutron and gamma ray dosimetry research.—These studies are directed toward development of improved techniques, procedures and systems for neutron and gamma dosimetry. Emphasis is placed on development of field systems for measurement of low-level radiation with the objective of achieving improving capability for the determination of nuclear power plant and reprocessing plant emissions. Neutron dosimetry research continues to merit primary attention.

Plutonium and other aerosol research.—The objective of these studies is to develop improved methods and technology for the measurement of plutonium, both in vivo and in situ and for the measurement and characterization of other radioactive particulates. A major effort is underway to improve our capability for measuring plutonium deposition in the lung. A second program is directed toward achieving an enhanced field measurement capability for the quantiative determination of plutonium in soil.

Radiation instrumentation research.—This program is directed toward development of improved radiation detectors. Current effort involves a continuing materials research on germanium in an effort to develop large volume radiation detectors. A concurrent effort on other potentially useful solid-state materials is underway to achieve a high atomic number, room temperature semi-conductor radiation detector.

MEDICAL DIAGNOSTIC THERAPEUTIC

The funds identified in this column represent the Biomedical Applications within the program Life Sciences Research and Biomedical Applications under the Assistant Administrator for Environment and Safety.

Medical applications of nuclear technology

The objectives of this research are to determine new uses of radiation, radioactive and enriched stable isotopes for the diagnosis and treatment of human disease.

The following elements are representative of the Program.

Research in nuclear medicine is being redirected so that the research not only addresses the needs of the medical community in general but also focuses more sharply on the ERDA energy-oriented mission, i.e., the development of new techniques to detect early signs of disease related to energy effluents.

Recent advances achieved in nuclear medicine instrumentation dictate a shift in the direction of this research.

Emphasis on new radionuclides and radioactively labeled agents is shifting toward the development of positron-labeled radiopharmaceuticals. These agents, used in combination with the new instrumentation, will permit actual localization in depth (tomography) of lesions and opens up a new field of organ function studies. A similar change in emphasis has been made already in the clinical nuclear medicine research and has yielded significant results. New techniques for the safe and rapid detection of blood clots in the lung and elsewhere in the body have been developed. New radiopharmaceuticals for the detection of tumors and metastatic lesions are being tested in the clinic. Non-invasive techniques for the early detection of heart disease and the quantitation of damage following heart attacks show considerable promise for patient management and in evaluation of patients for cardiac surgery.

A new center for emergency treatment of radiation accident victims is now operational in Oak Ridge, Tennessee. This unique facility will also serve as a central facility for the training of physicians and paramedical personnel in the management of patients exposed to harmful doses of ionizing radiation.

Research in radiotherapy is mainly focused on the use of heavy particles. These particles have theoretical advantages in their effectiveness to destroy tumor cells. A major effort is being conducted at the LBL Bevalac high energy, heavy ion accelerator to explore the actual usefulness of these particles. This is a cooperative effort with the National Cancer Institute.

Research on the production and use of stable isotopes

The objective of this effort is to increase the production of enriched stable isotopes of carbon, oxygen and nitrogen and the development of new uses for these isotopes. Their applications in medical, biological and environmental research areas appear most promising. Application of stable isotopes under conditions where radiation is undesirable, such as pediatrics or mass screening in preventive medicine, are considered of great interest. Excellent promise was demonstrated in the use of stable isotopes to trace the movement of gases released from, for instance, fossil fueled power plants. These studies could yield important information on how pollutants are dispersed in the environment and reach man.

Strong interest by the National Institutes of Health has resulted in the establishment of a jointly supported National Stable Isotope Resource at the Las Alamos Scientific Laboratory.

Medical devices

Two implantable versions of the bench-model of the artificial heart were recently completed and are being tested in the laboratory. Subsequent animal testing is planned for the near future to evaluate the physiological acceptability and system performance. Preliminary experiments in animals with an electrically driven pump have demonstrated the feasibility in principle of total heart replacement by a mechanical device. Major problems in both the engineering and biocompatibility aspects of the device have yet to be solved.

CRITERIA AND/OR STANDARDS DEVELOPMENT

This program supports and provides the means for the development of ERDA safety standards, criteria, and guidelines. These standards, in turn, provide a backbone on which operations can be run in an orderly, efficient and safe manner. They also serve as the yardstick against which performance can be measured. The program assures that the specified procedures, steps, operating limits, functions, etc., are based on sound logic, accepted practices, supportive analytical work, and data research. This eliminates the possibility of reliance on untested methods or ideas.

SURVEILLANCE OF FACILITIES AND SITES (MONITORING AND/OR SURVEILLANCE)

This program supports efforts aimed at the determination of hazards and their level of severity to people, property and the environment. Through the use of improved procedures, hardware, systems, and monitoring techniques, a broad spectrum of hazardous elements is isolated and measured, and the existing and potential impact is evaluated. In addition, we maintain an Aerial Measuring System (AMS), formerly called Aerial Radiological Monitoring System (ARMS), is a continuing program for remote sensing data acquisition. The capability of remote sensing of naturally occurring radiation in the environment and of contamination whose type and amount are influenced by activities of man is expected to continue This capability is ERDA's primary emergency response to the loss of radioactive sources or large accidental releases of radioactivity or other hazardous materials, should such losses or releases occur. Rapid evaluation of the consequences of an accident situation is possible through detailed documentation of prior base-line surveys of ERDA and licensed nuclear facilities.

These base-line surveys are conducted by high technology personnel using a wide assortment state-of-the-art remote sensing equipment designed for rapid installation on a mix of aircraft (both fixed wing and helicopters). In addition to gaining the base-line data, these surveys provide that operational experience which is essential for the constant improvement of personnel expertise and equipment performance. This evolutionary process has allowed for the application of many remote sensing techniques to the monitoring of nonnuclear energy effluents and constituents.

Question 1. What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Answer. EPA was created in 1970 and given responsibility for setting generally applicable environmental radiation standards. To date, the only radiation standards promulgated under this authority has been Title 40 CFR 190 "Environmental Radiation Protection Standards for Nuclear Power Operations," which pertains to nuclear facilities involved in the nuclear power industry and which has imposed some controversial restrictions on nuclear power plants and fuel reprocessing plants.

The responsibility and authority of the now defunct Federal Radiation Council, to make recommendations to the President concerning radiation protection standards for use by Federal agencies was also transferred to EPA but, as yet, EPA has not submitted any new recommendations under this authority.

EPA has since been granted statutory authority to regulate radioactive materials other than those regulated by the NRC under the Atomic Energy Act (AEA), in liquid effluents and surface water (by the Federal Water Pollution Control Act) and in ground water and drinking water (by the Safe Drinking Water Act). The question of EPA's authority to regulate radioactivity in liquid effluents from facilities that are regulated by NRC under the AEA was contested in litigation and the Supreme Court held (COPIRG v. Train) that EPA did not have such regulatory authority under the provisions of the Federal Water Pollution Control Act.

In 1975 the Atomic Energy Commission was abolished and its regulatory authorities under the Atomic Energy Act were transferred to the newly created Nuclear Regulatory Commission (NRC). AEC's research development and operational functions were transferred to the newly created Energy Research and Development Administration.

The changes described above have not substantially changed ERDA's research, development and operational functions in the radiation area. However, there have been some changes as a result of the transfer of FRC's responsibility to EPA in regard to the development of Federal radiation standards. These changes have resulted in some confusion regarding responsibilities for setting radiation protection standards. The confusion appears to lie primarily in the area of EPA vs. NRC authority for promulgating regulations pertaining to radioactivity emanating from facilities regulated by NRC. This confusion has led to some litigation and one Supreme Court decision (*COPIRG* v. *Train*).

Question 2. Would you please describe the nature of the contacts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and federal agencies?

Answer. There are routine contacts between ERDA's field offices and state groups in those states where ERDA operates nuclear facilities. These contacts involve the exchange of information including routine reporting and discussion of effluent and environmental monitoring data collected in or in the vicinity of ERDA facilities primarily by ERDA contractors but in some instances by the states as well. State and regional groups visit ERDA facilities and are thoroughly apprised of operations at ERDA facilities that are conducted or planned and may be of interest to state and regional groups. Since the states have no regulatory jurisdiction over radioactivity at Federal facilities, there has not been any confusion concerning their respective responsibilities.

Question 3. Would you please provide the Committee with your thoughts on how the present regulation programs could be improved. Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Answer. There is one area in which the present regulation of radiation programs could be improved to avoid the confusion that exists regarding responsibilities for esablishing radiation standards. We believe it is appropriate that generally applicable environmental radiation standards, based on protection of the health and safety of the public, should be developed and promulgated by the Environmental Protection Agency. However, since long established policy in nuclear energy research, development and operations require that radiation exposure to the public, the environment, and radiation workers be maintained as far below prescribed standards as practicable, the determination of practicability should be the responsibility of the agencies responsible for developing the nuclear technology and regulating its commercial application. This is an important distinction since the application of nuclear energy is one of if not the only industrial application of technology that is totally regulated beginning with site selection, facility design, and construction and continuing on through operation, decontamination and decommissioning and disposal. Decisions on what is practicable require extensive knowledge and detailed evaluation of the design and operation of the nuclear technology and the costs and effects of alternate methods for containing and controlling radiation exposure within and outside of the facility. Such decisions cannot be based solely on environmental or on economic considerations and would require unnecessary costly and counterproductive regulatory authority if more than one agency has responsibility for such decisions. The responsibilities for setting radiation environmental standards for determining how far below such standards additional controls are practicable, is separable and should be kept separate. Clearly, the promulgation of regulations governing both environmental radiation protection and regulation of nuclear facilities should be subject to review by all agencies concerned, as is presently the case. However, while there is need for clearer definition of these responsibilities than presently exists, it is not clear whether legislation is necessary to accomplish this.

Question 4. What is your reaction to the proposals to consolidate all Federal radiation activities into one Federal radiation agency?

Answer. Proposals to consolidate all Federal regulation activities into one Federal radiation agency do not appear to be workable. It is appropriate that the responsibilities for radiation activities be handled in the same way as the various responsibilities for handling of other potentially hazardous materials. Specifically, the responsibiliy for public health, environmental protection, and energy technology development aspects of radiation and radioactivity are appropriately assigned to those departments and agencies that have similar responsibilities with regard to other public health, environmental or energy-related matters. There appears to be no sound rationale for treating Federal radiation activities any differently than other potentially hazardous activities.

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE,
NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH,
Rockville, Md.

Hon. WARREN G. MAGNUSON,
Chairman, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: This is in response to your letter of May 26, requesting information about NIOSH research and technical assistance programs in the area of radiation. We do not have authority under the Radiation Control for Health and Safety Act of 1968 (P.L. 90–602), which concerns the public health aspects of radiation emissions from electronic products. We do, however, have an active program under authority of the Occupational Safety and Health Act of 1970 (P.L. 91–596). This letter will respond to the specific questions you raised in your letter. In addition, we are enclosing a list and brief description of our radiation projects for the years specified.

Question 1. What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Answer. Prior to passage of the Occupational Safety and Health Act of 1970, the predecessor organization of NIOSH operated under the general research authorities of the Public Health Service Act. Between 1968 and 1971 a small portion of our resources were devoted to the radiation effort. Following passage of the Act, NIOSH was given specific responsibility to develop recommended standards for exposure to a broad range of occupational hazards, including radiation.

These recommended standards are transmitted to the Occupational Safety and Health Administration (OSHA) in the Department of Labor (DOL), which is responsible for setting and enforcing the standards.

In fiscal year 1972 NIOSH established a Radiation Section in what is now the Division of Biomedical and Behavioral Science. The section performs research at our laboratory in Cincinnati, Ohio on the biological effects of radiation. Research areas include ionizing radiation sources subject to OSHA regulation (machine-produced radiation and naturally-occurring radio-nuclides), as well as non-ionizing radiation sources (microwave, radio-frequency (RF), laser, visible, ultraviolet, infrared, sound and ultrasound). Other radiation research is conducted by NIOSH in the areas of field studies, hazard evaluations, control technology, and personal protective equipment and instrumentation development. Additionally, our staff provides training and technical assistance in the radiation areas to personnel of other organizations.

Criteria documents recommending standards for occupational exposure have been developed for noise and ultraviolet radiation. Documents planned for fiscal year 1977 through 81 include radiofrequency and microwave radiation, infrared radiation and ultrasonic radiation. In addition, a criteria document will be developed for welding and brazing processes, including radiation exposure aspects. Planned for transmittal to OSHA beyond fiscal year 1981 is the visible radiation criteria document.

Question 2. Would you please describe the nature of the contracts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and Federal agencies?

Answer. NIOSH has interacted on radiation matters with other Federal agencies, including the Bureau of Radiological Health and the Bureau of Medical Devices of the Food and Drug Administration, the National Cancer Institute and the National Institute of Environmental Health Sciences of the National Institutes of Health, the Occupational Safety and Health Administration and the Bureau of Labor Statistics of the Department of Labor, the Atomic Energy Commission (and its successors), the Environmental Protection Agency, the Electromagnetic Radiation Management Advisory Council of the Office of Telecommunications Policy, the Department of Defense, the Federal Aviation Administration, the National Bureau of Standards, the Internal Revenue Service of the Treasury Department, the Mine Enforcement and Safety Administration, and the National Academy of Sciences.

Although we are not required to coordinate our work with states, NIOSH has worked cooperatively with state programs whenever possible. In FY 75, we conducted a study to identify potential problems associated with the use of non-medical radiation sources under jurisdiction of the Occupational Safety and Health Act. The study was based on reports of radiation surveys and accidents in nine states, and could not have been performed without state cooperation. We also send a representative to the annual conference of State Radiation Control Program Directors.

Additional interaction with state groups regarding radiation matters is evident from the list of our radiation projects (appended). To the best of my knowledge, there is no confusion concerning respective responsibilities between state agencies and NIOSH (or other Federal agencies).

We also have worked with universities, trade associations such as the American Welding Society, organized labor, the International Microwave Power Institute, the American Industrial Hygiene Association, the Health Physics Society, the American Public Health Association, the American Conference of Governmental Industrial Hygienists, the Institute of Electrical and Electronic Engineers, the American National Standards Institute, and similar professional groups, radiation equipment manufacturers, and foreign and international agencies, such as the Ministry of Health and Welfare in Canada, and the World Health Organization.

Question 3. Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved. Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Answer. NIOSH maintains a general awareness of the activities of other agencies, and feels that, despite the fact that we are not aware of any deficiencies in the regulation of radiation programs, increased coordination among Federal radiation programs would be useful. As an example, the Electromagnetic Radiation Management Advisory Council (ERMAC) of the Office of Telecommunications Policy has established the Biological Effects of Nonionizing Electromagnetic Radiation Committee (BENER) which reviews and coordinates microwave and radiofrequency biological research activities in Federal agencies. Through periodic meetings, all agencies are briefed on ongoing programs to minimize duplication of effort and maximize interagency cooperation.

Within NIOSH, funding for radiation programs has increased steadily since the Radiation Section was formed. The present funding level is appropriate for in-house studies considering existing personnel resources. We have scheduled criteria documents that should provide the basis for complete health standards for the most important occupational exposures to radiation.

Question 4. What is your reaction to the proposals to consolidate all Federal radiation activities into one Federal radiation agency?

Answer. Although NIOSH would support further coordination among Federal radiation activities (as outlined Question 3), we would foresee certain problems in consolidating all such programs in a single agency. The primary problem would be that the existing radiation programs have been established for different purposes in response to different Congressional mandates. NIOSH focuses on an integrated occupational safety and health program to protect workers; for example, radiation in the workplace can generate toxic gases. Ultraviolet radiation from a welding torch can generate toxic quantities of ozone and oxides of nitrogen. To have one agency responsible for the gaseous environment, while another agency is responsible for the radiation environment could result in failure to recognize and correct a potentially dangerous situation. NIOSH believes it is more important to use a broad spectrum of scientific specialties to protect workers on a functional or total basis than to separate the disciplines and try to protect workers on a piecemeal, or hazard-by-hazard basis. Also, since workers are exposed simultaneously to chemical and physical hazards (including radiation), which may produce additive or synergistic effects, we believe that less protection would be afforded employed men and women if all radiation programs were put in one Federal agency. The answer to this question reflects the views of NIOSH and not necessarily those of the Department.

Sincerely yours,

EDWARD J. BAIER, *Deputy Director.*

NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH

Fiscal year—Category and brief description	Man-years	Extramural funds	Total funds
NONIONIZING RADIATION PROJECTS			
1968—Monitoring (laser) Survey of laser installations to evaluate potential laser harzards.	2.0	0	25,000
1968—State/Federal liaison (laser) Survey of laser installations to determine need for State regulatory control.	2.0	0	25,000
1968—State/Federal liaison (microwave) Review of health programs, survey techniques and instrumentation employed in microwave hazard evaluations.	1.0	0	25,000
1969—Monitorng (laser) Survey of laser installations to evaluate potential laser hazards, publish results of survey.	2.0	0	30,000
1969—State/Federal liaison (laser) Survey of laser installations to determine need for State regulatory control; publish results of study.	2.0	0	30,000
1972—Criteria and/or standards development (UV) Award contract to Franklin Institute Research Laboratories to develop UV criteria document; publish document (HSM 73-11009).	.5	20,000	30,000
1972—Monitoring (ultrasound) Award contract to determine potential hazards and select survey instrumentation.	.4	40,000	50,000
1972—Monitoring (UV, RF) Surveys of RF sources in forest products industry, development of UV monitor (CBS); Interagency Agreement (IA) with NBS to provide calibrated lamps for UV facility.	.3	46,000	56,000
1973—State/Federal liaison (all types) Development of nonionizing radiation safety course for OSHA industrial hygienists; 2 presentations of course.	1.0	0	15,000
1973—State/Federal liaison (microwave) Development of microwave calibration system to calibrate OSHA microwave instruments.	.1	0	10,000
1973—Monitoring (UV) Monitor UV meter (CBS) contract; develop test procedures for evaluation of meter.	1.5	5,000	33,650
1973—State/Federal liaison (RF/microwave) Review of current OSHA microwave standard especially below 300 MHz; evaluate need for standard for pulsed electromagnetic radiation.	1.65	0	58,065
1974—State/Federal liaison (microwave) Development of microwave calibration system to calibrate OSHA microwave instruments.	.2	0	10,000
1974—Other (training) (all types) Presentation of nonionizing radiation safety course.	.3	0	4,000
1974—Health effects (UV) Award contract for UV ocular effects (300–400 nm).	1.2	120,000	134,500
1974—Monitoring (UV) Award new UV meter contract (KA), establish calibration facility, obtain standard detectors from NBS; publish UV (CBS) report.	1.3	101,460	138,460
1974—Monitoring (RF) Award IA to NBS for RF instrumentation; survey of industrial RF applications.	1.9	40,500	83,500
1975—State/Federal liaison (microwave) Development of microwave calibration system to calibrate OSHA microwave instruments.	.2	0	10,000
1975—Other (training) (all types) Development of package training course and manual on nonionizing radiation safety; presentation of 2 courses.	.5	70,000	80,000
1975—State/Federal liaison (laser) Initiate IA with Army to classify lasers according to draft OSHA laser standard; technical request from OSHA Office of Standards.	.4	4,000	13,800
1975—Health effects (UV) Monitor UV ocular effects contract.	.7	0	14,050
1975—Health effects (RF) Initiate IA with USAF School of Aerospace Medicine to study biochemical changes due to RF exposure, establish need for phantom modeling work.	.8	50,000	71,560
1975—Health effects (visible) Organize symposium to identify potential safety and health hazards from decreased lighting levels; define research needs; publish symposium proceedings (75–142).	.4	0	19,800
1975—Monitoring (RF) Surveys of industrial RF sources; initiate IA with NBS to design RF synthesizer for instrument evaluation and calibration dosimetry and animal bioeffects studies; publish NBS reports on instrument design (75–127, 140).	.9	85,000	119,000
1975—Monitoring (UV) Monitor UV meter contract (KA), evaluation of black light sources, initiate IA with NBS for calibration of standards, publish NBS report of IA (75–131).	.9	5,700	33,450

See footnotes at end of table.

NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH—Continued

Fiscal year—Category and brief description	Man-years	Extramural funds	Total funds
NONIONIZING RADIATION PROJECTS—Continued			
1975—Monitoring (IR) Purchase equipment to measure IR sources.	.8	0	35,400
1976—Health effects (UV) Monitor UV ocular effects contract; determination of feasibility of identifying UV-induced skin cancer.	.6	0	16,250
1976—Monitoring (RF) Surveys of industrial RF sources (data will provide input for RF bioeffects studies; publish NBS report on development of RF synthesizer (76-160).	1.4	0	42,650
1976—Monitoring (optical) Surveys of optical radiation from welding arcs; contract with American Welding Society provides input on radiation and other hazards from welding for criteria document development.	1.1	25,000	59,000
1976—Health effects (RF) Monitor IA with USAF School of Aerospace Medicine; develop contract with Georgia Tech to determine dielectric properties of human and animal tissue to be used for dosimetry in bio-effects studies.	.7	45,000	63,475
1976—State/Federal liaison (laser) Monitor IA with Army for laser compendium; publish compendium (76-183).	.5	5,000	35,350
1976—Other (literature review) (all NIR)[1] Review of literature on radiation induced cancer, and prepare state-of-art report under contract to Franklin Institute Research Laboratories.	.1	34,500	36,800
1976—State/Federal liaison (microwave) Calibration of OSHA microwave instruments.	.8	0	15,000
1976—Other (training) (all types) 2 presentations of nonionizing radiation safety course.	.1	0	10,000
1977—Health effects (RF) Initiate IA with NBS for RF dosimetry system; plan and initiate RF teratology study; work with Navy on pancreatic cancer study; publish 3 reports from USAF School of Aerospace Medicine (77-146).	2.0	91,000	163,450
1977—Other (literature review) (all NIR) Monitor contract with Franklin Institute.	.3	0	14,175
1977—Health effects (IR, UV) Monitor welding contract; award contract to determine threshold levels for IR ocular effects; monitor UV ocular effects contract; survey of VDT's[2] in regard to alleged radiation-induced cataracts; publish 1st part of UV ocular effects study (77-130).	3.5	52,000	154,000
1977—State/Federal liaison (RF/microwave) Development of RF calibration system to calibrate OSHA RF instruments; calibration of OSHA microwave instruments.	.9	0	20,000
1977—Other (training) (all types) 1 presentation of nonionizing radiation safety course.	.1	0	5,000
1978—Health effects (RF) Continue RF teratology study.	4.0	91,000	268,000
1978—Monitorig (optical) Monitor IR and welding contracts.	2.0	0	92,000
1978—State/Federal liaison (RF/microwave) Development of RF calibration system to calibrate OSHA instruments; calibration of OSHA microwave instruments.	.9	0	15,000
IONIZING RADIATION PROJECTS[3]			
1969—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	21.3	146,000	537,700
1970—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	21.5	137,000	509,000
1971—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	9.7	122,000	568,000
1971—State/Federal liaison (X-ray) Development of X-ray calibration system to calibrate OSHA survey instruments.	.1	0	1,000
1972—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	4.2	62,000	220,000
1972—Monitoring (X-rays) Survey of industrial X-ray facilities in Ohio with FDA/BRH.	.3	0	50,000
1972—State/Federal liaison (X-ray) Development of X-ray calibration system to calibrate OSHA survey instruments.	.1	0	1,000
1973—State/Federal liaison (X-ray) Development of X-ray calibration system to calibrate OSHA survey instruments.	.1	0	15,000

Footnotes at end of table.

IONIZING RADIATION PROJECTS—Continued			
1973—State/Federal liaison (all types) Review of current OSHA standards; program planning.	1.1	0	20,350
1973—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	4.1	0	117,000
1973—State/Federal liaison (all types) Development of ionizing radiation safety course for OSHA industrial hygienists; 2 presentations of course.	1.0	0	15,000
1974—Monitoring (X-rays) Set-up airport baggage X-ray study with FAA; identify other areas of concern.	.6	0	13,000
1974—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	3.5	0	78,000
1974—Other (training) (all types) Presentation of ionizing radiation safety course.	.3	0	4,000
1974—State/Federal liaison (X-ray) Calibration of OSHA survey instruments.	.1	0	2,000
1975—Monitoring (all types) Initiate contract with Teknekron to study occupational exposure to ionizing radiation sources; surveyed State records for employer violations, accidents, employee doses.	.4	70,000	84,600
1975—Other (training) (all types) Development of package training course on ionizing radiation safety; presentation of 2 courses.	.5	65,000	75,000
1975—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	3.0	0	52,000
1975—State/Federal liaison (X-ray) Calibration of OSHA survey instruments.	.1	0	5,000
1976—Monitoring (all types) Complete airport baggage X-ray study.	.4	0	13,050
1976—Other (literature review) (all types) Summary report of radiation-induced cancer under contract to Franklin Institute.	.1	11,500	13,500
1976—Other (training) (all types) 2 presentations of ionizing radiation safety course.	.1	0	10,000
1976—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	1.2	0	24,000
1976—State/Federal liaison (X-ray) Calibration of OSHA survey instruments.	.2	0	5,000
1977—State/Federal liaison (X-ray) Calibration of OSHA survey instruments.	.2	0	5,000
1977—Monitoring (all types) Complete Teknekron study; recommendations are being evaluated; sent to ANSI N43 subcommittee of industrial radiography; publish Teknekron report and airport baggage study (77-105, 142).	1.0	0	23,500
1977—Other (literature review) (all types) Monitor contract with Franklin Institute report due in fiscal year 1978; publish report.	.1	0	4,725
1977—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	2.0	0	52,000
1977—Other (training) (all types) 1 presentation of ionizing radiation short course.	.1	0	5,000
1978—Collection and/or analysis of health data (uranium) Industry-wide study of uranium miners and millers to determine hazards from exposure to radon daughter products.	2.1	0	52,000
1978—State/Federal liaison (X-ray) Calibration of OSHA survey instruments.	.2	0	2,000
Radiation program total:			
Nonionizing	37.9	846,000	1,850,000
Ionizing	79.7	602,000	2,559,000

NIR—Nonionizing radiation.

[2] VDT—Video display tenical.

[3] In addition to the projects listed, contracts existed with the States of Utah (fiscal year 1968–76), New Mexico (fiscal year 1969–73), and Wyoming (fiscal year 1970–71) for: analysis of epidemiological data on uranium miners; development of an experimental uranium mine; monitoring of uranium mines for radon daughter products physical examinations (including spectrum cytology) of uranium miners; and a study of lead to tin excretion in urine of uranium miners. Contracts also existed (fiscal year 1973–74) with Battelle Northwest for calculations on actual radiation dosage to lungs of uranium miners, and evaluation of methods for setting standards for radon daughter products. Under Public Law-480 authority, contracts existed over the period (fiscal year 1963–74) in Yugoslavia for a uranium miner epidemiological study, and animal and human studies on lead to excretion in the urine following exposure to uranium mine environments.

COMMENT BY ROBERT DUDNICK, ASSOCIATE DIRECTOR OF RESEARCH AND INFORMATION, THE NEWSPAPER GUILD, AFL–CIO, WASHINGTON, D.C.

On June 28, 1977, Dr. Elliott Harris testified to the Committee on behalf of the National Institute for Occupational Safety and Health's Division of Biomedical and Behavioral Science, of which he is the director.

A portion of Dr. Harris' testimony is incomplete and could, if not commented upon, lead those interested in radiation and occupational health to possibly erroneous conclusions.

It is perfectly true, as Dr. Harris has testified, that at our request NIOSH conducted a survey "to measure the radiation emissions from the cathode ray tube (CRT) of video display terminals (VDT) used in a newspaper composition room (sic) where two young employees developed bilateral cataracts."

He adds that levels of optical and RF radiation measured "were several orders of magnitude below existing occupational exposure guidelines."

What Dr. Harris does not say is that The Newspaper Guild did not and does not accept the survey results which his testimony presents as unchallenged. Consultants to the Guild's international office and to its New York Local 3 have grave reservations about the results, methodology and instrumentation.

These reservations were so strongly expressed that Local 3 brought the matter to arbitration. The arbitrator has ordered that a new, non-NIOSH test be conducted at the subject newspaper, the New York Times. The test is pending.

The Newspaper Guild and its Local 3 do not accept the NIOSH findings at the New York Times because there seems to us to be a reasonable doubt as to their accuracy. We do not dismiss the NIOSH report out of hand. We simply believe that we must adopt the most conservative, worst-case position in order to represent the interests of our members.

It is our view, therefore, that the NIOSH survey and the analysis of it as presented in the exhibit attached to this comment indicate that much more research is required before the subject can be laid to rest in the manner in which Dr. Harris attempted to dispose of it.

NIOSH had submitted an interim and final report to The Newspaper Guild and Local 3. In the exhibit that follows this statement, reference is made to both reports. Reference also is made to Dr. Milton Zaret, who commented on the NIOSH reports as consultant to Local 3. The material in the exhibit was developed and written by Dr. Victor Alexander, a physician and industrial hygienist assigned to the AFL–CIO Industrial Union Department. Dr. Alexander has acted as consultant to the Guild's international office in this matter. He submitted these findings to The Newspaper Guild on June 6, 1977.

ANALYSIS OF THE NIOSH NEW YORK TIMES VDT/CRT SURVEY

(By Victor Alexander, M.D.)

The final report from NIOSH on the New York Times Visual Display Terminal/Cathode Ray Tube (VDT/CRT) Survey is significantly modified from its initial version. The content is improved, but a number of defects remain. Pertinent comments will be offered below following the format of the Final Report. A summary will include information on VDT/CRT radiation hazards developed during the analysis of the report in conversations with scientists at Harvard School of Public Health, FDA Laboratory, Winchester, Mass., Bureau of Radiological Health, Rockville, Md., and the Hewlett-Packard Instrument Company.

The first significant change in the report involves the frequency bands in the electromagnetic (EM) spectrum to be surveyed. In the final report for theoretical reasons NIOSH claims the VDT/CRT equipment can't generate emissions with frequencies above 250 Megahertz (MHz). Each of the scientists contacted agreed with his basic supposition, in disagreement with Dr. Zaret's contention (letter of May 3, page 1). However, no one specifically had knowledge of actual measurements made under circumstances of mechanical malfunction. The point is of practical importance because the frequency range of microwaves is 30 MHz-300 Gigahertz (GHz). Furthermore, health effects on the eye have been found only from 915 MHz–10 GHz in the microwave region. Therefore if the machines are not capable of generating emissions above 250 MHz, the source of the cataracts must be sought in another portion of the EM spectrum.

The interim version of the NIOSH report claims to have measured microwave exposure (compare Interim Report, Page 2 with Final Report, Page 6). In fact, the NIOSH survey equipment will operate only from 10 MHz–500 MHz (HP 5303B Frequency Counter, EDM–2 electric field density meter, Narda 8607 magnetic field detector) missing not only the great majority of the microwave band, but *all* of the range in which health effects have been reported. NIOSH's own manual (Industrial Environment-Evaluation and Control 1973, Page 373) recommends a survey instrument responsive to wavelengths from 20 Kilohertz (KHz) to 12.4 GHz.

On theoretical grounds it seems unlikely the equipment would generate microwave emissions, but no reference to field studies measuring levels has been obtained, so perhaps this is an open question. In any event, no acceptable evaluation of microwave emissions has been made by this survey.

The survey instruments chosen for the ultraviolet (UV), visible, infrared (IR), and radiofrequency (RF) emissions seem generally appropriate to the task. Hewlett-Packard did report that the H–P5303B Frequency Counter is only moderately sensitive, and would not be the instrument of choice, suggesting that a spectrum analyzer would be a better selection.

There is no documentation for the choice of 2–3 centimeters (cm) as the distance from the VDT for measurements to be taken. No estimated shape or character of the radiation field, or near/far field profile is offered. In many studies such preliminary calculations are made to better define the best sampling distances.

During the survey on the Telco VDT there was interference from an unidentified source preventing use of the most sensitive scale (Final Report, Page 7). Yet in Table I (Final Report, Page 8) NIOSH reports results using precisely that most sensitive scale. Therefore one cannot rely on the accuracy of the reported integrated UV irradiance of 2.0 x 10–9 Watts cm^2, which in fact is already the highest value for the three VDTs measured, without considering the possible underestimation error due to the electrical interference.

The spectroradiometer was used to survey wavelengths of 350–1150 Nanometers (nm) for coverage of the visible and near infrared spectra. The usual reported extent of the near IR band is 700–1400 nm (NIOSH Industrial Environment, Page 366). This discrepancy is not consistent with the implied goal of a complete evaluation of potential radiation hazards (Final Report, Page 1), requested by the New York Times management.[1]

A frequency between 1 and 2 MHz was detected on the Telco VDT, but no quantitation of the energy levels could be obtained because the survey equipment does not operate below 10 MHz. This is pertinent since it is in precisely the range of 1–30 MHz that health effects are least well defined, and the smallest amount of research and data are available.

The description of the survey instruments carefully states the spectroradiometer measures UV wavelengths from 200–400 nm. Yet no values are reported for wavelengths below 300 nm. In effect, the survey was conducted for UV wavelengths from 300–400 nm. The peak of relative effectiveness for UV induced photokeratitis is 280 nm, that of skin carcinogenisis in man is approximately 295 nm (NIOSH Industrial Environment, Page 360). No effects of this kind are postulated in the present situation; the survey is again incomplete, ignoring areas of well-demonstrated biological effect.

An emission at 27 MHz from the Harris VDT was detected. NIOSH notes that at 12 cm the signal was not detectable (Final Report, Page 11). The strength at 2 cm is not recorded. Yet in the summary Table 6 (Final Report, Page 17) the maximum measured level is given as not detectable. The Instrumentation and Procedure section (Final Report, Page 6) clearly states that RF measurements were to be made at 2–3 cm, without any indication of modifying conditions. It is arguable at what particular distance measurements ought to be performed. But to offer the conclusions in Table 6 is playing fast and loose with the survey conditions the report writers set for themselves. A similar criticism applies for electrical field strength measurements reported in Table 2 (Final Report, Page 10).

Certain comparative measurements on other VDT's in the building were made; but only for luminance, and the RF band. The inciting cause for the survey was the report of cataracts in two VDT workers. The probable etiology of occupational cataracts, if the employee's cataracts are job related, would lead to measurement of exactly those EM bands not measured for comparison—that is, UV, IR, and microwave as the more potent cataractogenic agents.

---

[1] In fact. the evaluation was requested by The Newspaper Guild and Local 3, Newspaper Guild of New York, with the assistance of the AFL–CIO Industrial Union Department.

Magnetic field measurements on the seventh floor yielded a value of 1 milliwatt/cm² (Final Report, Page 13). This result was dismissed as caused by a nearby radio station because similar readings were obtained in an adjoining room and near window ledges. Each of four scientists contacted was concerned at this relatively high value. The speculation in the report for the source of emission is not supported by any evidence whatever. Further measurements in the Times building, on other floors, and a serious attempt to trace the origin of the emission are clearly and unmistakeably called for. The report is silent. To then estimate the value of magnetic field levels as zero is not justifiable.

X-ray measurements at the Times were not performed during this survey because results from a study at the Baltimore Sun are available (Final Report, Pages 2 and 3). The introduction to the Final Report (Page 2) states that the survey was done on 125 VDTs in Baltimore. The results reported in the main text are that 20% of the VDTs were measured on all six sides. It is not clear whether 20% of the 125 VDTs were measured, each on all sides, or all 125 were measured, 20% on all sides. Either way, fewer machines than expected were measured reducing the value of the results. Furthermore, only 75 machines in Baltimore were Harris 1500A models similar to those at the Times; there were no Telco or Incoterm models.

The report draws conclusions about radiation levels solely from ranges and maximum values for VDT emissions and background, without reporting any mean, average or distribution. No conclusions can be drawn from such incomplete data.

A second significant change in the report drafts is the use of a different reference standard for X-ray exposure. The interim report claimed the Sun results were less than the FDA standard for television receivers of .5 milliroentgens (mr) per hour. (Interim Report, Page 1). In fact the results in the final version (Final Report, Page 17) may very well conceal exposures of .5 mr/hr if the results were completely reported. (Maximum radiation measured .85 mr/hr, minimum background .16 mr/hr). However, a new standard of 2.5 mr/hr from OSHA is used (Final Report, Page 17). Where there are conflicting standards, good practice requires the use of the more stringent requirement. The data presented do not substantiate the report's conclusions about lack of possible X-ray exposure from VDTs.

The Harris VDT has a cathode ray tube which operates at a potential of 23–33 Kilowatts. The Bureau of Radiological Health scientists contacted reported that any such tube operating at greater than 20 KV is a potential X-ray source. They indicated their desire to make an independent survey of the VDT/CRT at the Times after a request by the Newspaper Guild in this matter. They expressed particular concern since these VDT/CRT sources are not legally classified as television receivers; and the BRH therefore lack enforcement powers, a situation they are actively trying to change.

There seems to be no significant disagreement that the cataracts referred to in the medical section are similar to and consistent with radiation induced injury. There is also no evidence for congenital, diabetic or steroid non-occupational causes. The NIOSH report claims to have eliminated the VDT as a possible source of radiation in the genesis of the cataracts. We cannot subscribe to that claim. The significant omissions, misstatements, and unwarranted conclusions of the report are reviewed above. The report is not only incomplete, but those areas covered are not always well done. The evidence offered does not decide the issues.

It appears that based on theoretical design criteria, microwaves are an unlikely VDT emission hazard. The UV band was not completely surveyed, nor was the IR range. Not enough is known about health effects in the RF spectrum and several frequencies in this range at 1 MHz, 20 MHz, and 27 MHz were found. A more persistent inquiry into the magnetic field reading on the seventh floor is indicated.

U.S. Department of Labor,
Washington, D.C., June 24, 1977.

Hon. Wendell H. Ford,
Chairman, Consumer Subcommittee, U.S. Senate,
Washington, D.C.

Dear Mr. Chairman: This is in response to your joint letter with Senator Adlai T. Stevenson on May 19, 1977, for information concerning the radiation control activities within the Occupational Safety and Health Administration (OSHA).

Response to the specific questions are enclosed as attachment A. Comments concerning the matrix like charts are enclosed as attachment B.

If we can assist you further please feel free to contact me.

Sincerely,

EULA BINGHAM,
Assistant Secretary,
Occupational Safety and Health.

Enclosures.

ATTACHMENT A

Question 1. What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e. inception of new agencies, transfer of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Answer. *a.* The major legislation for us in this period is our enabling legislation, the Occupational Safety and Health Act of 1970 (OSH Act). Pursuant to it OSHA has promulgated standards applicable to general industry concerning both ionizing and non-ionizing radiation. For ionizing radiation, these standards (enclosure 1) are basically those adopted by incorporation from regulations promulgated under the Walsh-Healy Public Service Contracts Act which in turn were derived from AEC regulations. Prior to OSHA coverage, the regulations extended to government contractors and to all employers in AEC-Agreement states. Under OSHA the coverage had been extended in 1971 to cover all employers nationwide.

The regulations for non-ionizing radiation, also first published in 1971, were derived from two voluntary national consensus standards of the American National Standards Institute (ANSI) concerning microwave radiation. These regulations (enclosure 2) established Federal regulation cover microwave exposure and were applicable to all employers.

b. OSHA safety and health regulations (enclosure 3) for the construction industry are issued under the authority of the Contracts Work Hours and Safety Standards Act of 1969. For ionizing radiation these standards reference 10 CFR 20 and are therefore essentially the same as the general industry standards. The limit for microwaves is also the same as for general industry. The construction standards include provisions to limit exposures to laser radiation.

c. The President's Reorganization Plan No. 3 of 1970 creating the Environmental Protection Agency (EPA) transferred to EPA some of the former responsibilities of the Federal Radiation Council. The EPA is charged to review and issue guidance to all Federal agencies concerning the regulation of exposure to ionizing radiation. Federal agencies then must stay within these guidelines when issuing regulations. OSHA's present regulations are well within the current guidelines; therefore this change of authority has had no effect on our activity to date.

Question 2. Would you please describe the nature of the contacts between your organization and state groups in the radiation field? Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of State and Federal agencies?

Answer. *a.* Generally no special coordination with state agencies is required or necessary in implementing our program. However, if a state becomes a State Plan State under section 18 of the OSH Act, then interaction is necessary to establish that the state plan is adequate and to monitor the execution of the state program with respect to the requirement that state standards and the enforcement of them is "at least as effective in providing safe and healthful employment" . . . . as the Federal standards. Without a state plan, state regulations are preempted by Federal OSHA regulations.

b. Confusion over jurisdiction has resulted in the case where on OSHA State Plan state is also an NRC-Agreement state. As a result, OSHA has held meetings with representatives of all states concerning the jurisdictional issues and the contents of ionizing radiation standards. OSHA has also maintained contact with the model regulation drafting activities by the states and with the Bureau of Radiological Health in FDA.

c. The NRC jurisdiction covers three classes of material known as "special nuclear material", "byproduct material" and "source material". OSHA jurisdiction covers such items as X-ray producing machinery, naturally occurring radioisotopes and radioisotopes produced with devices such as cyclotrons.

Question 3. Would you please provide the committee with your thoughts on how the present regulation of radiation programs could be improved? Are there any present deficiences of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Answer. *a.* With the exception of the jurisdictional issue discussed above, OSHA believes the present allocation of responsibilities for radiation regulation is generally satisfactory. However, emphasis should continue to be placed on interagency coordination of radiation programs to promote consistency among the regulations and to avoid unwarranted overlap of activities.

b. OSHA has announced its intention to simplify and update our existing standards, many of which had been adopted from voluntary consensus standards or from the regulations of other Federal Agencies. The OSHA radiation standards are among those standards and would be considered for improvement under this project.

c. OSHA was recently reorganized, creating an Office of Physical Agents Standards under the Directorate of Health Standards Programs. The Office's responsibility will be for development of all OSHA physical agent standards, including radiation standards. We are in the process of staffing that office to provide a more effective program for development of these standards. In addition, OSHA is increasing both the numbers and quality of our health enforcement staff, which will improve our effectiveness in ensuring compliance with our radiation standards.

Question 4. What is your reaction to the proposals to consolidate all Federal radiation activities into one Federal Radiation Agency?

Answer. As you are aware, the Administration is considering reorganizing the Executive Branch Departments to better effectuate the authorities of these agencies. Until completion of this review, we do not believe it is appropriate to comment on possible legislative proposals for reorganization.

NOTES TO MATRIX INFORMATION

1. OSHA does not perform or sponsor original research projects. The National Institute for Occupational Safety and Health (NIOSH) in DHEW generally does this for the field of occupational safety and health.

2. Ecological and environmental effects are to be considered in the preparation of environmental impact statements for individual standards projects. No environmental impact statements have been prepared for ionizing or non-ionizing radiation standards projects to date, but would be prepared before new standards are issued.

3. This is outside the jurisdiction of OSHA.

4. Criteria development is performed by NIOSH and submitted to OSHA in "Criteria Documents" which are used as part of the basis for formulating standards. Data presented are for man-years devoted to standards development, including estimates for supervision and clerical support.

5. Numbers include staff of State Programs national office, regional office staff, and state plan monitors at area offices, prorated to the proportion of inspections devoted to radiation of each type expressed as man-weeks.

6. Licensing and certification are not performed by OSHA. Numbers of inspections performed concerning radiation are shown. Data prior to FY 74 would be very difficult to compile due to differences in recordkeeping procedures at that time.

7. Numbers of measurements taken to support the inspections shown in previous column.

8. Collection of health data in the form of literature review and consultation with experts and the analysis of the resulting information is performed as a part of our standards development actiivty which is reflected in column 5 "Criteria and or standards development."

9. "L"=lasers; "uv"=ultraviolet; "mw"=microwaves.

10. No extramural funds are involved. Data on these tables reflect only federal activity and do not include activity by state personnel operating under State Plans. Note that OSHA was not formed until 1971.

(c) Ground returns and machine grounding.

(1) A ground return cable shall have a safe current carrying capacity equal to or exceeding the specified maximum output capacity of the arc welding or cutting unit which it services. When a single ground return cable services more than one unit, its safe current carrying capacity shall equal or exceed the total specified maximum output capacities of all the units which it services.

(2) Structures or pipe lines, except pipe lines containing gases or flammable liquids or conduits containing electrical circuits, may be used as part of the ground return circuit, provided that the pipe or structure has a current carrying capacity equal to that required by subparagraph (1) of this paragraph.

(3) When a structure or pipe line is employed as a ground return circuit, it shall be determined that the required electrical contact exists at all points. The generation of an arc, sparks or heat at any point shall cause rejection of the structure as a ground circuit.

(4) When a structure or pipe line is continuously employed as a ground return circuit, all joints shall be bonded, and periodic inspections shall be conducted to ensure that no condition of electrolysis or fire hazard exists by virtue of such use.

(5) The frames of all arc welding and cutting machines shall be grounded either through a third wire in the cable containing the circuit conductor or through a separate wire which is grounded at the source of the current. Grounding circuits, other than by means of the vessel's structure, shall be checked to ensure that the circuit between the ground and the grounded power conductor has resistance low enough to permit sufficient current to flow to cause the fuse or circuit breaker to interrupt the current.

(6) All ground connections shall be inspected to ensure that they are mechanically strong and electrically adequate for the required current.

(d) Operating instructions.

Employers shall instruct employees in the safe means of arc welding and cutting as follows:

(1) When electrode holders are to be left unattended, the electrodes shall be removed and the holders shall be so placed or protected that they cannot make electrical contact with employees or conducting objects.

(2) Hot electrode holders shall not be dipped in water, since to do so may expose the arc welder or cutter to electric shock.

(3) When the arc welder or cutter has occasion to leave his work or to stop work for any appreciable length of time, or when the arc welding or cutting machine is to be moved, the power supply switch to the equipment shall be opened.

(4) Any faulty or defective equipment shall be reported to the supervisor.

(e) Shielding.

Whenever practicable, all arc welding and cutting operations shall be shielded by noncombustible or flame-proof screens which will protect employees and other persons working in the vicinity from the direct rays of the arc.

1915.37—USES OF FISSIONABLE MATERIAL IN SHIP REPAIR

(a) In ship repair and related activities involving the use of and exposure to sources of ionizing radiation not only on conventionally powered but also on nuclear powered vessels, the applicable provisions of the Atomic Energy Commission's Standards for Protection Against Radiation (10 CFR Part 20), relating to protection against occupational radiation exposure, shall apply.

(b) Any activity which involves the use of radioactive material, whether or not under

TABLE D-2—PERMISSIBLE NOISE EXPOSURES

Duration per day, hours:	*Sound level dBA slow response*
8	90
6	92
4	95
3	97
2	100
1½	102
1	105
½	110
¼ or less	115

(2)

(i) When the daily noise exposure is composed of two or more periods of noise exposure of different levels, their combined effect should be considered, rather than the individual effect of each. Exposure to different levels for various periods of time shall be computed according to the formula set forth in subdivision (ii) of this subparagraph.

(ii)

$$F_6 = \frac{T_1}{L_1} + \frac{T_2}{L_2} + \cdots + \frac{T_n}{L_n}$$

where:

F_6 = The equivalent noise exposure factor.

T = The period of noise exposure at any essentially constant level.

L = The duration of the permissible noise exposure at the constant level (from Table D-2).

If the value of F_6 exceeds unity (1) the exposure exceeds permissible levels.

(iii) A sample computation showing an application of the formula in subdivision (ii) of this paragraph is as follows. An employee is exposed at these levels for these periods:

110 dba ¼ hour.
100 dba ½ hour.
90 dba 1½ hour.

$$F_6 = \frac{1/4}{1/2} + \frac{1/2}{2} + \frac{1\tfrac{1}{2}}{8}$$

$$F_6 = 0.500 + 0.25 + 0.188$$
$$F_6 = 0.938$$

Since the value of F_6 does not exceed unity, the exposure is within permissible limits.

(e) Exposure to impulsive or impact noise should not exceed 140 dB peak sound pressure level.

1926.53—IONIZING RADIATION

(a) In construction and related activities involving the use of sources of ionizing radiation, the pertinent provisions of the Atomic Energy Commission's Standards for Protection Against Radiation (10 CFR Part 20), relating to protection against occupational radiation exposure, shall apply.

(b) Any activity which involves the use of radioactive materials or X-rays, whether or not under license from the Atomic Energy Commission, shall be performed by competent persons specially trained in the proper and safe operation of such equipment. In the case of materials used under Commission license, only persons actually licensed, or competent persons under direction and supervision of the licensee, shall perform such work.

1926.54—NONIONIZING RADIATION

(a) Only qualified and trained employees shall be assigned to install, adjust, and operate laser equipment.

(b) Proof of qualification of the laser equipment operator shall be available and in possession of the operator at all times.

(c) Employees, when working in areas in which a potential exposure to direct or reflected laser light greater than 0.005 watts (5 milliwatts) exists, shall be provided with antilaser eye protection devices as specified in Subpart E of this part.

(d) Areas in which lasers are used shall be posted with standard laser warning placards.

(e) Beam shutters or caps shall be utilized, or the laser turned off, when laser transmission is not actually required. When the laser is left unattended for a substantial period of time, such as during lunch hour, overnight, or at change of shifts, the laser shall be turned off.

(f) Only mechanical or electronic means shall be used as a detector for guiding the internal alignment of the laser.

(g) The laser beam shall not be directed at employees.

(h) When it is raining or snowing, or when there is dust or fog in the air, the operation of laser systems shall be prohibited where practicable; in any event, employees shall be kept out of range of the area of source and target during such weather conditions.

(i) Laser equipment shall bear a label to indicate maximum output.

(j) Employees shall not be exposed to light intensities above:

(1) Direct staring: 1 micro-watt per square centimeter;

(2) Incidental observing: 1 milliwatt per square centimeter;

(3) Diffused reflected light: 2½ watts per square centimeter.

(k) Laser unit in operation should be set up above the heads of the employees, when possible.

(l) Employees shall not be exposed to microwave power densities in excess of 10 milliwatts per square centimeter.

1926.55—GASES, VAPORS, FUMES, DUSTS, AND MISTS

(a) Exposure of employees to inhalation, ingestion, skin absorption, or contact with any material or substance at a concentration above those specified in the "Threshold Limit Values of Airborne Contaminants for 1970" of the American Conference of Governmental Industrial Hygienists, shall be avoided.

(b) To achieve compliance with paragraph (a) of this section, administrative or engineering controls must first be implemented whenever feasible. When such controls are not feasible to achieve full compliance, protective equipment or other protective measures shall be used to keep the exposure of employees to air contaminants within the limits prescribed in this section. Any equipment and technical measures used for this purpose must first be approved for each particular use by a competent industrial hygienist or other shall be protected by means of rubber and friction tapes or other equivalent insulation.

(c) Ground returns and machine grounding.

(1) A ground return cable shall have a safe current carrying capacity equal to or exceeding the specified maximum output capacity of the arc welding or cutting unit which it services. When a single ground return cable services more than one unit, its safe current carrying capacity shall equal or exceed the total specified maximum output capacities of all the units which it services.

(2) Structures or pipe lines, except pipe lines containing gases or flammable liquids or conduits containing electrical circuits, may be used as part of the ground return circuit, provided that the pipe or structure has a current carrying capacity equal to that required by subparagraph (1) of this paragraph.

(3) When a structure of pipe line is employed as a ground return circuit, it shall be determined that the required electrical contact exists at all joints. The generation of an arc, sparks or heat at any point shall cause rejection of the structure as a ground circuit.

(4) When a structure or pipe line is continuously employed as a ground return circuit, all joints shall be bonded, and periodic inspections shall be conducted to ensure that no condition of electrolysis or fire hazard exists by virtue of such use.

(5) The frames of all arc welding and cutting machines shall be grounded either through a third wire in the cable containing the circuit conductor or through a separate wire which is grounded at the source of the current. Grounding circuits, other than by means of the vessel's structure, shall be checked to ensure that the circuit between the ground and the grounded power conductor has resistance low enough to permit sufficient current to flow to cause the fuse or circuit breaker to interrupt the current.

(6) All ground connections shall be inspected to ensure that they are mechanically strong and electrically adequate for the required current.

(d) Operating instructions.

Employers shall instruct employees in the safe means of arc welding and cutting as follows:

(1) When electrode holders are to be left unattended, the electrodes shall be removed and the holders shall be so placed or protected that they cannot make electrical contact with employees or conducting objects.

(2) Hot electrode holders shall not be dipped in water, since to do so may expose the arc welder or cutter to electric shock.

(3) When the arc welder or cutter has occasion to leave his work or to stop work for any appreciable length of time, or when the arc welding or cutting machine is to be moved, the power supply switch to the equipment shall be opened.

(4) Any faulty or defective equipment shall be reported to the supervisor.

(e) Shielding.

Whenever practicable, all arc welding and cutting operations shall be shielded by noncombustible or flame-proof screens which will protect employees and other persons working in the vicinity from the direct rays of the arc.

1916.37—USES OF FISSIONABLE MATERIAL IN SHIPBUILDING

(a) In shipbuilding and related activities involving the use of an exposure to sources of ionizing radiation not only on conventionally powered but also on nuclear powered vessels, the applicable provisions of the Atomic Energy Commission's Standards for Protection Against Radiation (10 CFR Part 20), relating to protection against occupational radiation exposure, shall apply.

(b) Any activity which involves the use of radioactive material, whether or not under license from the Atomic Energy Commission, shall be performed by competent persons specially trained in the proper and safe operation of such equipment. In the case of materials used under Commission license, only persons actually licensed, or competent persons under direction and supervision of the licensee, shall perform such work.

(2) If the variations in noise level involve maxima at intervals of 1 second or less, it is to be considered continuous.

(3) In all cases where the sound levels exceed the values shown herein, a continuing, effective hearing conservation program shall be administered.

1910.96—IONIZING RADIATION

(a) Definitions applicable to this section.

(1) "Radiation" includes alpha rays, beta rays, gamma rays, X-rays, neutrons, high-speed electrons, high-speed protons, and other atomic particles; but such term does not include sound or radio waves, or visible light, or infrared or ultraviolet light.

(2) "Radioactive material" means any material which emits, by spontaneous nuclear disintegration, corpuscular or electromagnetic emanations.

(3) "Restricted area" means any area access to which is controlled by the employer for purposes of protection of individuals from exposure to radiation or radioactive materials.

(4) "Unrestricted area" means any area access to which is not controlled by the employer for purposes of protection of individuals from exposure to radiation or radioactive materials.

(5) "Dose" means the quantity of ionizing radiation absorbed, per unit of mass, by the body or by any portion of the body. When the provisions in this section specify a dose during a period of time, the dose is the total quantity of radiation absorbed, per unit of mass, by the body or by any portion of the body during such period of time. Several different units of dose are in current use. Definitions of units used in this section are set forth in subparagraphs (6) and (7) of this paragraph.

(6) "Rad" means a measure of the dose of any ionizing radiation to body tissues in terms of the energy absorbed per unit of mass of the tissue. One rad is the dose corresponding to the absorption of 100 ergs per gram of tissue (1 millirad (mrad) = 0.001 rad).

(7) "Rem" means a measure of the dose of any ionizing radiation to body tissue in terms of its estimated biological effect relative to a dose of 1 roentgen (r) of X-rays (1 millirem (mrem) =0.001 rem). The relation of the rem to other dose units depends upon the biological effect under consideration and upon the conditions for irradiation. Each of the following is considered to be equivalent to a dose of 1 rem:

(i) A dose of 1 (r) due to X- or gamma radiation;

(ii) A dose of 1 rad due to X-, gamma, or beta radiation;

(iii) A dose of 0.1 rad due to neutrons or high energy protons;

(iv) A dose of 0.05 rad due to particles heavier than protons and with sufficient energy to reach the lens of the eye;

(v) If it is more convenient to measure the neutron flux, or equivalent, than to determine the neutron dose in rads, as provided in subdivision (iii) of this subparagraph, 1 rem of neutron radiation may, for purposes of the provisions in this section be assumed to be equivalent to 14 million neutrons per square centimeter incident upon the body; or, if there is sufficient information to estimate with reasonable accuracy the approximate distribution in energy of the neutrons, the incident number of neutrons per square centimeter equivalent to 1 rem may be estimated from Table G-17:

TABLE G-17—NEUTRON FLUX DOSE EQUIVALENTS

Neutron energy (million electron volts (Mev))	Number of neutrons per square centimeter equivalent to a dose of 1 rem (neutrons/cm^2)	Average flux to deliver 100 millirem in 40 hours (neutrons/cm^2 per sec.)
Thermal	970 × 10^6	670
0.0001	720 × 10^6	500
0.005	820 × 10^6	570
0.02	400 × 10^6	280
0.1	120 × 10^6	80
0.5	43 × 10^6	30
1.0	26 × 10^6	18
2.5	29 × 10^6	20
5.0	26 × 10^6	18
7.5	24 × 10^6	17
10	24 × 10^6	17
10 to 30	14 × 10^6	10

(8) For determining exposures to X- or gamma rays up to 3 Mev., the dose limits specified in this section may be assumed to be equivalent to the "air dose." For the purpose of this section "air dose" means that the dose is measured by a properly calibrated appropriate instrument in air at or near the body surface in the region of the highest dosage rate.

(b) Exposure of individuals to radiation in restricted areas.

(1) Except as provided in subparagraph (2) of this paragraph, no employer shall possess, use, or transfer sources of ionizing radiation in such a manner as to cause any individual in a restricted area to receive in any period of one calendar quarter from sources in the employer's possession or control a dose in excess of the limits specified in Table G-18:

TABLE G-18

	Rems per calendar quarter
Whole body: Head and trunk; active blood-forming organs; lens of eyes; or gonads	1¼
Hands and forearms; feet and ankles	18¾
Skin of whole body	7½

(2) An employer may permit an individual in a restricted area to receive doses to the whole body greater than those permitted under subparagraph (1) of this paragraph, so long as:

(i) During any calendar quarter the dose to the whole body shall not exceed 3 rems; and

(ii) The dose to the whole body, when added to the accumulated occupational dose to the whole body, shall not exceed 5 (N–18) rems, where "N" equals the individual's age in years at his last birthday; and

(iii) The employer maintains adequate past and current exposure records which show that the addition of such a dose will not cause the individual to exceed the amount authorized in this subparagraph. As used in this subparagraph, "dose to the whole body" shall be deemed to include any dose to the whole body, gonad, active bloodforming organs, head and trunk, or lens of the eye.

(3) No employer shall permit any employee who is under 18 years of age to receive in any period of one calendar quarter a dose in excess of 10 percent of the limits specified in Table G–18.

(4) "Calendar quarter" means any 3-month period determined as follows:

(i) The first period of any year may begin on any date in January: *Provided*, That the second, third, and fourth periods accordingly begin on the same date in April, July, and October, respectively, and that the fourth period extends into January of the succeeding year, if necessary to complete a 3-month quarter. During the first year of use of this method of determination, the first period for that year shall also include any additional days in January preceding the starting date for the first period; or

(ii) The first period in a calendar year of 13 complete, consecutive calendar weeks; the second period in a calendar year of 13 complete consecutive weeks; the third period in a calendar year of 13 complete, consecutive calendar weeks; the fourth period in a calendar year of 13 complete, consecutive calendar weeks. If at the end of a calendar year there are any days not falling within a complete calendar week of that year, such days shall be included within the last complete calendar week of that year. If at the beginning of any calendar year there are days not falling within a complete calendar week of that year, such days shall be included within the last complete calendar week of the previous year; or

(iii) The four periods in a calendar year may consist of the first 14 complete, consecutive calendar weeks; the next 12 complete, consecutive calendar weeks, the next 14 complete, consecutive calendar weeks, and the last 12 complete, consecutive calendar weeks. If at the end of a calendar year there are any days not falling within a complete calendar week of that year, such days shall be included (for purposes of this section) within the last complete calendar week of the year. If at the beginning of any calendar year there are days not falling within a complete calendar week of that year, such days shall be included (for purposes of this section) within the last complete week of the previous year.

(5) No employer shall change the method used by him to determine calendar quarters except at the beginning of a calendar year.

(c) Exposure to airborne radioactive material.

(1) No employer shall possess, use or transport radioactive material in such a manner as to cause any employee, within a restricted area, to be exposed to airborne radioactive material in an average concentration in excess of the limits specified in Table 1 of Appendix B to 10 CFR Part 20. The limits given in Table 1 are for exposure to the concentrations specified for 40 hours in any workweek of 7 consecutive days. In any such period where the number of hours of exposure is less than 40, the limits specified in the table may be increased proportionately. In any such period where the number of hours of exposure is greater than 40, the limits specified in the table shall be decreased proportionately.

(2) No employer shall possess, use, or transfer radioactive material in such a manner as to cause any individual within a restricted area, who is under 18 years of age, to be exposed to airborne radioactive material in an average concentration in excess of the limits specified in Table II of Appendix B to 10 CFR Part 20. For purposes of this subparagraph, concentrations may be averaged over periods not greater than 1 week.

(3) "Exposed" as used in this paragraph means that the individual is present in an airborne concentration. No allowance shall be made for the use of protective clothing or equipment, or particle size.

(d) Precautionary procedures and personal monitoring.

(1) Every employer shall make such surveys as may be necessary for him to comply with the provisions in this section. "Survey" means an evaluation of the radiation hazards incident to the production, use, release, disposal, or presence of radioactive materials or other sources of radiation under a specific set of conditions. When appropriate, such evaluation includes a physical survey of the location of materials and equipment, and measurements of levels of radiation or concentrations of radioactive material present.

(2) Every employer shall supply appropriate personnel monitoring equipment, such as film badges, pocket chambers, pocket dosimeters, or film rings, to, and shall require the use of such equipment by:

(i) Each employee who enters a restricted area under such circumstances that he receives, or is likely to receive, a dose in any calendar quarter in excess of 25 percent of the applicable value specified in paragraph (b)(1) of this section; and

(ii) Each employee under 18 years of age who enters a restricted area under such circumstances that he receives, or is likely to receive, a dose in any calendar quarter in excess of 5 percent of the applicable value specified in paragraph (b)(1) of this section; and

(iii) Each employee who enters a high radiation area.

(3) As used in this section:

(i) "Personnel monitoring equipment" means devices designed to be worn or carried by an individual for the purpose of measuring the dose received (e.g., film badges, pocket chambers, pocket dosimeters, film rings, etc.);

(ii) "Radiation area" means any area, accessible to personnel, in which there exists radiation at such levels that a major portion of the body could receive in any 1 hour a dose in excess of 5 millirem, or in any 5 consecutive days a dose in excess of 100 millirem; and

(iii) "High radiation area" means any area, accessible to personnel, in which there exists radiation at such levels that a major portion of the body could receive in any one hour a dose in excess of 100 millirem.

(e) Caution signs, labels, and signals.

(1) General.

(i) Symbols prescribed by this paragraph shall use the conventional radiation caution colors (magenta or purple on yellow background). The symbol prescribed by this paragraph is the conventional three-bladed design:

(ii) In addition to the contents of signs and labels prescribed in this paragraph, employers may provide on or near such signs and labels any additional information which may be appropriate in aiding individuals to minimize exposure to radiation or to radioactive material.

RADIATION SYMBOL

1. Cross-hatched area is to be magenta or purple.
2. Background is to be yellow.

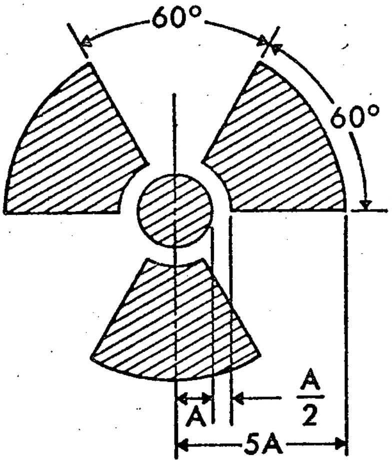

FIGURE G–10

(2) Radiation area. Each radiation area shall be conspicuously posted with a sign or signs bearing the radiation caution symbol described in subparagraph (1) of this paragraph and the words:

CAUTION
RADIATION AREA

(3) High radiation area.

(i) Each high radiation area shall be conspicuously posted with a sign or signs bearing the radiation caution symbol and the words:

CAUTION
HIGH RADIATION AREA

(ii) Each high radiation area shall be

equipped with a control device which shall either cause the level of radiation to be reduced below that at which an individual might receive a dose of 100 millirems in 1 hour upon entry into the area or shall energize a conspicuous visible or audible alarm signal in such a manner that the individual entering and the employer or a supervisor of the activity are made aware of the entry. In the case of a high radiation area established for a period of 30 days or less, such control device is not required.

(4) Airborne radioactivity area.

(i) As used in the provisions of this section, "airborne radioactivity area" means:

(a) Any room, enclosure, or operating area in which airborne radioactive materials, composed wholly or partly of radioactive material, exist in concentrations in excess of the amounts specified in column 1 of Table 1 of Appendix B to 10 CFR Part 20 or

(b) Any room, enclosure, or operating area in which airborne radioactive materials exist in concentrations which, averaged over the number of hours in any week during which individuals are in the area, exceed 25 percent of the amounts specified in column 1 of Table 1 of Appendix B to 10 CFR Part 20.

(ii) Each airborne radioactivity area shall be conspicuously posted with a sign or signs bearing the radiation caution symbol described in subparagraph (1) of this paragraph and the words:

CAUTION
AIRBORNE RADIOACTIVITY AREA

(5) Additional requirements.

(i) Each area or room in which radioactive material is used or stored and which contains any radioactive material (other than natural uranium or thorium) in any amount exceeding 10 times the quantity of such material specified in Appendix C to 10 CFR Part 20 shall be conspicuously posted with a sign or signs bearing the radiation caution symbol described in subparagraph (1) of this paragraph and the words:

CAUTION
RADIOACTIVE MATERIALS

(ii) Each area or room in which natural uranium or thorium is used or stored in an amount exceeding 100 times the quantity of such material specified in 10 CFR Part 20 shall be conspicuously posted with a sign or signs bearing the radiation caution symbol described in subparagraph (1) of this paragraph and the words:

CAUTION
RADIOACTIVE MATERIALS

(6) Containers.

(i) Each container in which is transported, stored, or used a quantity of any radioactive material (other than natural uranium or thorium) greater than the quantity of such material specified in Appendix C to 10 CFR Part 20 shall bear a durable, clearly visible label bearing the radiation caution symbol described in subparagraph (1) of this paragraph and the words:

CAUTION
RADIOACTIVE MATERIALS

(ii) Each container in which natural uranium or thorium is transported, stored, or used in a quantity greater than 10 times the quantity specified in Appendix C to 10 CFR Part 20 shall bear a durable, clearly visible label bearing the radiation caution symbol described in subparagraph (1) of this paragraph and the words:

CAUTION
RADIOACTIVE MATERIALS

(iii) Notwithstanding the provisions of subdivisions (i) and (ii) of this subparagraph a label shall not be required:

(a) If the concentration of the material in the container does not exceed that specified in column 2 of Table 1 of Appendix B to 10 CFR Part 20, or

(b) For laboratory containers, such as beakers, flasks, and test tubes, used transiently in laboratory procedures, when the user is present.

(iv) Where containers are used for storage, the labels required in this subparagraph shall state also the quantities and kinds of radioactive materials in the containers and the date of measurement of the quantities.

(f) Immediate evacuation warning signal.

(1) Signal characteristics.

(i) The signal shall be a midfrequency complex sound wave amplitude modulated at a subsonic frequency. The complex sound wave in free space shall have a fundamental frequency (f_1) between 450 and 500 hertz (Hz) modulated at a subsonic rate between 4 and 5 hertz.

(ii) The signal generator shall not be less than 75 decibels at every location where an individual may be present whose immediate, rapid, and complete evacuation is essential.

(iii) A sufficient number of signal units shall be installed such that the requirements of subdivision (ii) of this subparagraph are met at every location where an individual may be present whose immediate, rapid, and complete evacuation is essential.

(iv) The signal shall be unique in the plant or facility in which it is installed.

(v) The minimum duration of the signal shall be sufficient to insure that all affected persons hear the signal.

(vi) The signal-generating system shall respond automatically to an initiating event without requiring any human action to sound the signal.

(2) Design objectives.

(i) The signal-generating system shall be designed to incorporate components which enable the system to produce the desired signal each time it is activated within one-half second of activation.

(ii) The signal-generating system shall be provided with an automatically activated secondary power supply which is adequate to simultaneously power all emergency equipment to which it is connected, if operation during power failure is necessary, except in those systems using batteries as the primary source of power.

(iii) All components of the signal-generating system shall be located to provide maximum practicable protection against damage in case of fire, explosion, corrosive atmosphere, or other environmental extremes consistent with adequate system performance.

(iv) The signal-generating system shall be designed with the minimum number of components necessary to make it function as intended, and should utilize components which do not require frequent servicing such as lubrication or cleaning.

(v) Where several activating devices feed activating information to a central signal generator, failure of any activating device shall not render the signal-generator system inoperable to activating information from the remaining devices.

(vi) The signal-generating system shall be designed to enhance the probability that alarm occurs only when immediate evacuation is warranted. The number of false alarms shall not be so great that the signal will come to be disregarded and shall be low enough to minimize personal injuries or excessive property damage that might result from such evacuation.

(3) Testing.

(i) Initial tests, inspections, and checks of the signal-generating system shall be made to verify that the fabrication and installation were made in accordance with design plans and specifications and to develop a thorough knowledge of the performance of the system and all components under normal and hostile conditions.

(ii) Once the system has been placed in service, periodic tests, inspections, and checks shall be made to minimize the possibility of malfunction.

(iii) Following significant alterations or revisions to the system, tests and checks similar to the initial installation tests shall be made.

(iv) Tests shall be designed to minimize hazards while conducting the tests.

(v) Prior to normal operation the signal-generating system shall be checked physically and functionally to assure reliability and to demonstrate accuracy and performance. Specific tests shall include:

(a) All power sources.

(b) Calibration and calibration stability.

(c) Trip levels and stability.

(d) Continuity of function with loss and return of required services such as AC or DC power, air pressure, etc.

(e) All indicators.

(f) Trouble indicator circuits and signals, where used.

(g) Air pressure (if used).

(h) Determine that sound level of the signal is within the limit of subparagraph (1)(ii) of this paragraph at all points that require immediate evacuation.

(vi) In addition to the initial startup and operating tests, periodic scheduled performance tests and status checks must be made to insure that the system is at all times operating within design limits and capable of the required response. Specific periodic tests or checks or both shall include:

(a) Adequacy of signal activation device.

(b) All power sources.

(c) Function of all alarm circuits and trouble indicator circuits including trip levels.

(d) Air pressure (if used).

(e) Function of entire system including operation without power where required.

(f) Complete operational tests including sounding of the signal and determination that sound levels are adequate.

(vii) Periodic tests shall be scheduled on the basis of need, experience, difficulty, and disruption of operations. The entire system should be operationally tested at least quarterly.

(viii) All employees whose work may necessitate their presence in an area covered by the signal shall be made familiar with the actual sound of the signal—preferably as it sounds at their work location. Before placing the system into operation, all employees normally working in the area shall be made acquainted with the signal by actual demonstration at their work locations.

(g) Exceptions from posting requirements.

Notwithstanding the provisions of paragraph (e) of this section:

(1) A room or area is not required to be posted with a caution sign because of the presence of a sealed source, provided the radiation level 12 inches from the surface of the source container or housing does not exceed 5 millirem per hour.

(2) Rooms or other areas in onsite medical facilities are not required to be posted with

caution signs because of the presence of patients containing radioactive material, provided that there are personnel in attendance who shall take the precautions necessary to prevent the exposure of any individual to radiation or radioactive material in excess of the limits established in the provisions of this section.

(3) Caution signs are not required to be posted at areas or rooms containing radioactive materials for periods of less than 8 hours: *Provided,* That

(i) The materials are constantly attended during such periods by an individual who shall take the precautions necessary to prevent the exposure of any individual to radiation or radioactive materials in excess of the limits established in the provisions of this section; and

(ii) Such area or room is subject to the employer's control.

(h) Exemptions for radioactive materials packaged for shipment.

Radioactive materials packaged and labeled in accordance with regulations of the Department of Transportation published in 49 CFR Chapter I, are exempt from the labeling and posting requirements of this subpart during shipment, provided that the inside containers are labeled in accordance with the provisions of paragraph (e) of this section.

(i) Instruction of personnel, posting.

(1) Employers regulated by the Atomic Energy Commission shall be governed by 10 CFR Part 20 standards. Employers in a State named in paragraph (p)(3) of this section shall be governed by the requirements of the laws and regulations of that State. All other employers shall be regulated by the following:

(2) All individuals working in or frequenting any portion of a radiation area shall be informed of the occurrence of radioactive materials or of radiation in such portions of the radiation area; shall be instructed in the safety problems associated with exposure to such materials or radiation and in precautions or devices to minimize exposure; shall be instructed in the applicable provisions of this section for the protection of employees from exposure to radiation or radioactive materials; and shall be advised of reports of radiation exposure which employees may request pursuant to the regulations in this section.

(3) Each employer to whom this section applies shall post a current copy of its provisions and a copy of the operating procedures applicable to the work conspicuously in such locations as to insure that employees working in or frequenting radiation areas will observe these documents on the way to and from their place of employment, or shall keep such documents available for examination of employees upon request.

(j) Storage of radioactive materials.

Radioactive materials stored in a nonradiation area shall be secured against unauthorized removal from the place of storage.

(k) Waste disposal.

No employer shall dispose of radioactive material except by transfer to an authorized recipient, or in a manner approved by the Atomic Energy Commission or a State named in paragraph (p)(3) of this section.

(l) Notification of incidents.

(1) **Immediate notification.** Each employer shall immediately notify the Assistant Secretary of Labor or his duly authorized representative, for employees not protected by the Atomic Energy Commission by means of 10 CFR Part 20; paragraph (p)(2) of this section, or the requirements of the laws and regulations of States named in paragraph (p)(3) of this section, by telephone or telegraph of any incident involving radiation which may have caused or threatens to cause:

(i) Exposure of the whole body of any individual to 25 rems or more of radiation; exposure of the skin of the whole body of any individual to 150 rems or more of radiation; or exposure of the feet, ankles, hands, or forearms of any individual to 375 rems or more of radiation; or

(ii) The release of radioactive material in concentrations which, if averaged over a period of 24 hours, would exceed 5,000 times the limit specified for such materials in Table II of Appendix B to 10 CFR Part 20.

(iii) A loss of 1 working week or more of the operation of any facilities affected; or

(iv) Damage to property in excess of $100,000.

(2) **Twenty-four hour notification.** Each employer shall within 24 hours following its occurrence notify the Assistant Secretary of Labor or his duly authorized representative for employees not protected by the Atomic Energy Commission by means of 10 CFR Part 20; paragraph (p)(2) of this section, or the requirements of the laws and applicable regulations of States named in paragraph (p)(3) of this section, by telephone or telegraph of any incident involving radiation which may have caused or threatens to cause:

(i) Exposure of the whole body of any individual to 5 rems or more of radiation; exposure of the skin of the whole body of any individual to 30 rems or more of radiation; or exposure of the feet, ankles, hands, or forearms to 75 rems or more of radiation; or

(ii) A loss of 1 day or more of the operation of any facilities; or

(iii) Damage to property in excess of $10,000.

(m) Reports of overexposure and excessive levels and concentrations.

(1) In addition to any notification required by paragraph (1) of this section each employer shall make a report in writing within 30 days to the Assistant Secretary of Labor or his duly authorized representative, for employees not protected by the Atomic Energy Commission by means of 10 CFR Part 20; or under paragraph (p)(2) of this section, or the requirements of the laws and regulations of States named in paragraph (p)(3) of this section, of each exposure of an individual to radiation or concentrations of radioactive material in excess of any applicable limit in this section. Each report required under this subparagraph shall describe the extent of exposure of persons to radiation or to radioactive material; levels of radiation and concentration of radioactive material involved, the cause of the exposure, levels of concentrations; and corrective steps taken or planned to assure against a recurrence.

(2) In any case where an employer is required pursuant to the provisions of this paragraph to report to the U.S. Department of Labor any exposure of an individual to radiation or to concentrations of radioactive material, the employer shall also notify such individual of the nature and extent of exposure. Such notice shall be in writing and shall contain the following statement: "You should preserve this report for future reference."

(n) Records.

(1) Every employer shall maintain records of the radiation exposure of all employees for whom personnel monitoring is required under paragraph (d) of this section and advise each of his employees of his individual exposure on at least an annual basis.

(2) Every employer shall maintain records in the same units used in tables in paragraph (b) of this section and Appendix B to 10 CFR Part 20.

(o) Disclosure to former employee of individual employee's record.

(1) At the request of a former employee an employer shall furnish to the employee a report of the employee's exposure to radiation as shown in records maintained by the employer pursuant to paragraph (n)(1) of this section. Such report shall be furnished within 30 days from the time the request

is made, and shall cover each calendar quarter of the individual's employment involving exposure to radiation or such lesser period as may be requested by the employee. The report shall also include the results of any calculations and analysis of radioactive material deposited in the body of the employee. The report shall be in writing and contain the following statement: "You should preserve this report for future reference."

(2) The former employee's request should include appropriate identifying data, such as social security number and dates and locations of employment.

(p) Atomic Energy Commission licensees—AEC contractors operating AEC plants and facilities—AEC agreement State licensees or registrants.

(1) Any employer who possesses or uses source material, byproduct material, or special nuclear material, as defined in the Atomic Energy Act of 1954, as amended, under a license issued by the Atomic Energy Commission and in accordance with the requirements of 10 CFR Part 20 shall be deemed to be in compliance with the requirements of this section with respect to such possession and use.

(2) AEC contractors operating AEC plants and facilities: Any employer who possesses or uses source material, byproduct material, special nuclear material, or other radiation sources under a contract with the Atomic Energy Commission for the operation of AEC plants and facilities and in accordance with the standards, procedures, and other requirements for radiation protection established by the Commission for such contract pursuant to the Atomic Energy Act of 1954 as amended (42 U.S.C. 2011 et seq.), shall be deemed to be in compliance with the requirements of this section with respect to such possession and use.

(3) AEC-agreement State licensees or registrants:

(i) **Atomic Energy Act sources.** Any employer who possesses or uses source material, byproduct material, or special nuclear material, as defined in the Atomic Energy Act of 1954, as amended (42 U.S.C. 2011 et seq.), and has either registered such sources with, or is operating under a license issued by, a State which has an agreement in effect with the Atomic Energy Commission pursuant to section 274(b) (42 U.S.C. 2021(b)) of the Atomic Energy Act of 1954, as amended, and in accordance with the requirements of that State's laws and regulations shall be deemed to be in compliance with the radiation requirements of this section, insofar as his possession and use of such material is concerned, unless the Secretary of Labor, after conference with the Atomic Energy Commission, shall determine that the State's program for control of these radiation sources is incompatible with the requirements of this section. Such agreements currently are in effect only in the States of Alabama, Arkansas, California, Kansas, Kentucky, Florida, Mississippi, New Hampshire, New York, North Carolina, Texas, Tennessee, Oregon, Idaho, Arizona, Colorado, Louisiana, Nebraska, Washington, Maryland, North Dakota, South Carolina, and Georgia.

(ii) **Other sources.** Any employer who possesses or uses radiation sources other than source material, byproduct material, or special nuclear material, as defined in the Atomic Energy Act of 1954, as amended (42 U.S.C. 2011 et seq.), and has either registered such sources with, or is operating under a license issued by a State which has an agreement in effect with the Atomic Energy Commission pursuant to section 274(b) (42 U.S.C. 2021(b)) of the Atomic Energy Act of 1954, as amended, and in accordance with the requirements of that State's laws and regulations shall be deemed to be in compliance with the radiation requirements of this section, insofar as his possession and use of such material is concerned, provided the State's program for control of these radiation sources is the subject of a currently effective determination by the Assistant Secretary of Labor that such program is compatible with the requirements of this section. Such determinations currently are in effect only in the States of Alabama, Arkansas, California, Kansas, Kentucky, Florida, Mississippi, New Hampshire, New York, North Carolina, Texas, Tennessee, Oregon, Idaho, Arizona, Colorado, Louisiana, Nebraska, Washington, Maryland, North Dakota, South Carolina, and Georgia.

(q) [Reserved]

(r) Radiation standards for mining.

(1) For the purpose of this paragraph, a "working level" is defined as any combination of radon daughters in 1 liter of air which will result in the ultimate emission of 1.3x10^5 million electron volts of potential alpha energy. The numerical value of the "working level" is derived from the alpha energy released by the total decay of short-lived radon daughter products in equilibrium with 100 picocuries of radon 222 per liter of air. A working level month is defined as the exposure received by a worker breathing air at one working level concentration for 4⅓ weeks of 40 hours each.

(2) Occupational exposure to radon daughters in mines shall be controlled so that no individual will receive an exposure of more than 2 working level months in any calendar quarter and no more than 4 working level months in any calendar year. Actual exposures shall be kept as far below these values as practicable.

(3)

(i) For uranium mines, records of environmental concentrations in the occupied parts of the mine, and of the time spent in each area by each person involved in an underground work shall be established and maintained. These records shall be in sufficient detail to permit calculations of the exposures, in units of working level months, of the individuals and shall be available for inspection by the Secretary of Labor or his authorized agents.

(ii) For other than uranium mines and for surface workers in all mines, subdivision (i) of this subparagraph will be applicable: *Provided, however,* That if no environmental sample shows a concentration greater than 0.33 working level in any occupied part of the mine, the maintenance of individual occupancy records and the calculation of individual exposures will not be required.

(4)

(i) At the request of an employee (or former employee) a report of the employee's exposure to radiation as shown in records maintained by the employer pursuant to subparagraph (3) of this paragraph, shall be furnished to him. The report shall be in writing and contain the following statement:

> This report is furnished to you under the provisions of the U.S. Department of Labor, Ionizing Radiation Safety and Health Standards (29 CFR 1910.96(r)). You should preserve this report for future reference.

(ii) The former employee's request should include appropriate identifying data, such as social security number and dates and locations of employment.

1910.97—NONIONIZING RADIATION

(a) Electromagnetic radiation.

(1) Definitions applicable to this paragraph.

(i) The term "electromagnetic radiation" is restricted to that portion of the spectrum commonly defined as the radio frequency region, which for the purpose of this specification shall include the microwave frequency region.

(ii) Partial body irradiation. Pertains to the case in which part of the body is exposed to the incident electromagnetic energy.

(iii) Radiation protection guide. Radiation level which should not be exceeded without careful consideration of the reasons for doing so.

(iv) The word "symbol" as used in this specification refers to the overall design, shape, and coloring of the rf radiation sign shown in figure G-11.

(v) Whole body irradiation. Pertains to the case in which the entire body is exposed to the incident electromagnetic energy or in which the cross section of the body is smaller than the cross section of the incident radiation beam.

(2) Radiation protection guide.

(i) For normal environmental conditions and for incident electromagnetic energy of frequencies from 10 MHz to 100 GHz, the radiation protection guide is 10 mW/cm.^{2} (milliwatt per square centimeter) as averaged over any possible 0.1-hour period. This means the following:

Power density: 10 mW./cm.^{2} for periods of 0.1-hour or more.
Energy density: 1 mW.-hr./cm.^{2} (milliwatt hour per square centimeter) during any 0.1-hour period.

This guide applies whether the radiation is continuous or intermittent.

(ii) These formulated recommendations pertain to both whole body irradiation and partial body irradiation. Partial body irradiation must be included since it has been shown that some parts of the human body (e.g., eyes, testicles) may be harmed if exposed to incident radiation levels significantly in excess of the recommended levels.

(3) Warning symbol.

(i) The warning symbol for radio frequency radiation hazards shall consist of a red isosceles triangle above an inverted black isosceles triangle, separated and outlined by an aluminum color border. The words "Warning—Radio-Frequency Radiation Hazard" shall appear in the upper triangle. See figure G-11.

(ii) American National Standard Safety Color Code for Marking Physical Hazards and the Identification of Certain Equipment, Z53.1-1953, shall be used for color specification. All lettering and the border shall be of aluminum color.

(iii) The inclusion and choice of warning information or precautionary instructions is at the discretion of the user. If such information is included it shall appear in the lower triangle of the warning symbol.

(4) Scope. This section applies to all radiations originating from radio stations, radar equipment, and other possible sources of electromagnetic radiation such as used for communication, radio navigation, and industrial and scientific purposes. This section does not apply to the deliberate exposure of patients by, or under the direction of, practitioners of the healing arts..

1910.98—EFFECTIVE DATES

(a) The provisions of this Subpart G shall become effective on August 27, 1971, except as provided in the remaining paragraphs of this section.

(b) The following provisions shall become effective on February 15, 1972:

§ 1910.94 (a)(2)(iii), (a)(3), (a)(4), (b), (c)(2), (c)(3), (c)(4), (c)(5), (c)(6)(i), (c)(6)(ii), (d)(1)(ii), (d)(3), (d)(4), (d)(5), and (d)(7).

(c) Notwithstanding anything in paragraph (a), (b), or (d) of this section, any provision in any other section of this subpart which contains in itself a specific effective date or time limitation shall become effective on such date

or shall apply in accordance with such limitation.

(d) Notwithstanding anything in paragraph (a) of this section, if any standard in 41 CFR Part 50-204, other than a national consensus standard incorporated by reference in § 50-204.2(a)(1), is or becomes applicable at any time to any employment and place of employment, by virtue of the Walsh-Healey Public Contracts Act, or the Service Contract Act of 1965, or the National Foundation on Arts and Humanities Act of 1965, any corresponding established Federal standard in this Subpart G which is derived from 41 CFR Part 50-204 shall also become effective, and shall be applicable to such employment and place of employment, on the same date.

1910.100—STANDARDS ORGANIZATIONS

Specific standards of the following organizations have been referenced in this subpart. Copies of the standards may be obtained from the issuing organization.

American Conference of Governmental Industrial Hygienists, 1014 Broadway, Cincinnati, OH 45202.
American National Standards Institute, 1430 Broadway, New York, NY 10018.
National Fire Protection Association, 60 Batterymarch Street, Boston, MA 02110.

1910.145—SPECIFICATIONS FOR ACCIDENT PREVENTION SIGNS AND TAGS

(a) Scope.

(1) These specifications apply to the design, application, and use of signs or symbols (as included in paragraphs (c) through (e) of this section) intended to indicate and, insofar as possible, to define specific hazards of a nature such that failure to designate them may lead to accidental injury to workers or the public, or both, or to property damage. These specifications are intended to cover all safety signs except those designed for streets, highways, railroads, and marine regulations. These specifications do not apply to plant bulletin boards or to safety posters.

(2) All new signs and replacements of old signs on or after August 31, 1971, shall be in accordance with these specifications.

(b) Definitions.

As used in this section, the word "sign" refers to a surface on which letters or other markings appear, prepared for the warning of, or safety instructions of, industrial workers or members of the public who may be exposed to hazards. Excluded from this definition, however, are news releases, displays commonly known as safety posters, and bulletins used for employee education.

(c) Classification of signs according to use.

(1) Danger signs.

(i) Danger signs should be used only where an immediate hazard exists. There shall be no variation in the type of design of signs posted to warn of specific dangers and radiation hazards.

(ii) All employees shall be instructed that danger signs indicate immediate danger and that special precautions are necessary.

(2) Caution signs.

(i) Caution signs shall be used only to warn against potential hazards or to caution against unsafe practices.

(ii) All employees shall be instructed that caution signs indicate a possible hazard against which proper precaution should be taken.

(3) Safety instruction signs. Safety instruction signs shall be used where there is a need for general instructions and suggestions relative to safety measures.

(d) Sign design and colors.

(1) Design features. The colors, proportions, and location of the identification panels on each sign shall be in accordance with this paragraph. All signs shall be furnished with rounded or blunt corners and shall be free from sharp edges, burrs, splinters, or other sharp projections. The ends or heads of bolts or other fastening devices shall be located in such a way that they do not constitute a hazard. When conditions warrant the use of a sign size not covered in the following tables, the ratio of the depth of the identifying panel (Danger, Caution, etc.) to the width of the sign shall be as established in Tables J–1 to J–4.

(2) Danger signs.

(i) The colors red, black, and white shall be those of opaque glossy samples as specified in Table 1 of Fundamental Specification of Safety Colors for CIE Standard Source "C", American National Standard Z53.1–1967.

(ii) Standard proportions shall be as indicated in Table J–1, and format shall be as in Fig. J–1.

(3) Radiation warning signs.

TABLE J-1—STANDARD PROPORTIONS FOR DANGER SIGNS

Sign size, inches Height Width	Black rectangular panel, inches Height Width	Red oval, inches Height Width	Word danger, height inches	Maximum space available for sign wording, inches

Fig. J-2
Radiation Warning Sign

(i) Standard color of the background shall be yellow; the panel, reddish purple with yellow letters; the symbol, reddish purple; any letters used against the yellow background shall be black. The colors shall be those of opaque glossy samples as specified in Table 1 of American National Standard, Z53.1–1967.

(ii) The standard symbol shall be as in Figure J-3. Method of dimensioning, design, and orientation of the standard symbol (one blade pointed downward and centered on the vertical axis) shall be executed as illustrated. The symbol shall be prominently displayed, and of a size consistent with the size of the equipment or material or area to which it is attached.

(iii) Format shall be as in Figure J-2. Sign proportions shall be the same as those for danger signs in Table J-1.

(4) Caution signs.

(i) Standard color of the background shall be yellow; and the panel, black with yel-

warn against potential hazards or to caution against unsafe practices. (See Fig. J-12.)

(ii) All employees should be instructed that Caution tags indicate a possible hazard against which proper precautions should be taken.

(6) Out of order tags. Out of Order tags should be used only for the specific purpose of indicating that a piece of equipment, machinery, etc., is out of order and to attempt to use it might present a hazard. (See Fig. J-13.)

(7) Radiation tags.

(i) The standard background for Radiation tags shall be yellow; the panel shall be reddish purple. Any letters used against the yellow background shall be black. The colors shall be those of opaque glossy samples as specified in Table 1, Fundamental Specification of Safety Colors for CIE Standard Source "C" American National Standard Safety Color Code for Marking Physical Hazards and the Identification of Certain Equipment, Z53.1-1967.

(ii) The method of dimension, design, and orientation of the standard symbol (one blade pointed downward and centered on the vertical axis) shall be executed as illustrated in Figure J-14. The symbol shall be prominently displayed and of a size consistent with the size of the equipment or area in which it is to be used.

(8) Biological hazard tags.

(i) The standard background color for the Biological Hazard symbol is optional as

(i) **General.** The requirements of paragraphs (a), (b), (d), (e), and (f) of this section shall be observed.

(ii) **X-ray inspection.** The use of X-rays and radioactive isotopes for the inspection of welded piping joints shall be in conformance with the American National Standard Safety Standard for Non-Medical X-ray and Sealed Gamma-Ray Sources. ANSI Z54.1-1963.

NATIONAL INSTITUTE OF ENVIRONMENTAL HEALTH SCIENCES,
Research Triangle Park, N.C., June 8, 1977.

Hon. WENDELL H. FORD,
Chairman, Consumer Subcommittee, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: The National Institute of Environmental Health Sciences (NIEHS) is pleased to provide you with the detailed material describing the NIEHS effort in radiation research. We have carefully followed the format which you provided with your letter of May 19. We hope these data will be helpful to you as you undertake your comprehensive review.

We are pleased to provide our brief responses.

Question 1 dealt with the effects of changes in public jurisdictions and posture between 1968 and 1977. The formation of new agencies such as the Environmental Protection Agency and the Energy Research and Development Administration with significantly increased regulatory responsibility has not affected our program directly. However, NIEHS has felt obliged to respond in a manner somewhat limited by available resources to additional emphasis and to the need for more research in the area of non-ionizing radiation. Further, with the enactment of the Radiation Control for Health and Safety Act, we recognize the need for additional long-term basic research to support the development of realistic standards.

Question 2 was concerned with the nature of contacts between state groups and NIEHS. Contacts with state radiation professionals is rather limited to occasional responses to requests for general information from both public and private sources at the state level and to participation by NIEHS professional staff in meetings with local health physics societies or with other relevant professional societies.

The third question dealt with the regulation of radiation programs. We understand this to be the coordination of radiation research supported and conducted by the federal government. Each federal agency has generally chosen the research projects and program priorities which respond to their specific mission statements. The general mission of the agency along with the general state of science in this field has dictated the composition of that agency's component of the total federal effort. The Office of Telecommunications Policy (OTP) has done an excellent job of bringing together a compilation of the current research projects in non-ionizing radiation. OTP has however not been able to formally coordinate research programs or to obtain the added resources necessary to fund the additional research needed. We recognize that one of the major problems in coordinating research exists because there are many different and diverse public agencies which have considerable official responsibility, but very small under-supported organizations to carry out the research required to meet their public responsibilities. This phenomenon has in many ways led to a self-imposed coordination activity. In this situation agencies are quite reluctant to duplicate efforts. We believe that the present funding level for all research is far short of that needed to adequately answer existing regulatory questions in a reasonable time. The OTP has indicated in their program analyses that the total federal effort is budgeted at about one-half of that required to fully meet responsibilities. We believe however that money alone will not meet the currently unmet needs. A major element in this effort will be the inducement of sufficient numbers of trained scientists into research activity in electromagnetic radiation effects.

In response to the fourth question we are concerned that there are a number of relatively small research efforts in various agencies which deal with the scientific problems related to radiation. We believe that there exist valid reasons for each of these agencies to have a radiation research activity. However we are concerned that the sum total effect of these activities may be less than their impact if they were aggregated. We would point out however that here would cerainly develop problems for agencies to meet mission requirements if their research capabilities were removed from them. It is doubtful that a single mission oriented agency would have the breadth of interest or the level of mutual confidence to successfully aggregate a radiation research program of the necessary magnitude. It may be possible however to approach this in a basic research agency such as the National Institutes of Health.

We appreciate the opportunity to provide the enclosed factual information to the Committee regarding NIEHS' radiation research effort and further, appreciate the opportunity to discuss our impressions regarding the federal organization of radiation research activities.

Sincerely,

DAVID P. RALL, M.D., Ph. D.,
Director.

PROJECT DESCRIPTIONS—FISCAL YEAR 1969

IONIZING AND NONIONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–69

Project title: Development of a Respiratory Tract Dose Model for Uranium Miners.

Studies to determine human health effects.

Total man-years. 0.45. Funding level: $19,800.

Project description: To develop a respiratory tract dose model that will provide reliable estimates of the dose to the basal cells of the bronchial epithelium in the case of inhalation of alpha emitters. A theoretical approach has been taken that requires identification of the relations between the important parameters involved in the assessment of the dose to the respiratory tract due to inhalation of alpha emitters. The model must be based to the extent possible on actual dose-effect data.

Ionizing Radiation—Project I2–69

Project title: Range and Linear Energy Transfer of Alpha Particles in Tissue.

Studies to determine human health effects.

Total man-years: 0.25. Funding level: $11,000.

Project description: To determine the range and linear energy transfer of alpha particles in tissue and to investigate the connection between those energy loss characteristics and biological effects.

Ionizing Radiation—Project I3–69

Project title: Research on the "Combined Effects of Inhalation of Uranium Ore Dust and Radon Daughters with Cigarette Smoke or Diesel Exhaust Fumes on the Lungs of Dogs and Hamsters." (Contract—Battelle Northwest-Pacific Northwest Laboratory.)

Studies to determine human health effects.

Funding level: $159,000.

Project description: As a major part of an integrated research program on the effects of exposure to radon and daughters on the development of lung cancer in uranium miners, the following animal studies were initiated:

1. Groups of hamsters are to be exposed to the following combinations: (*a*) Radon daughters on room air nuclei, (*b*) radon daughters on carnotite ore dust plus diesel exhaust fumes; (*c*) diesel and exhaust fumes alone.

Analysis and control of concentrations of radon and daughters, composition of ore dust, and concentrations of other toxic agents in the diesel oil exhaust fumes will be made by the most advanced techniques available. After being exposed to alpha particle irradiation to predetermined cumulative dosage levels comparable to the WLM exposures of high-level exposed miners, the animals will be maintained for life for the observation of pathological changes, particularly lung cancer.

2. To test specifically the possible synergistic effects of radon and daughters and cigarette smoking, studies were initiated on three groups of 18 dogs as described below:

(*a*) Dogs exposed to radon and daughters on carnotic ore—exposure for 4 hours per day, 7 days per week at concentrations of 15 nanocuries per liter;

(*b*) Dogs exposed to radon plus daughters on ore as in (a), plus two working shifts of smoking (total of 10 cigarettes per day with resting on alternate hours);

(*c*) Two shifts of smoking only, 10 cigarettes per day as in (b).

Regular clinical, radiological, radiographic, and hematological examinations will be made during and after the smoking and radon exposures. The dogs, except for one in each group to be sacrificed for early histopathological studies, will be held for their remaining life span with observations of pulmonary changes and lung cancer as the end point.

Ionizing Radiation—Project I4–69

Project title: Radon Progeny Inhalation Exposures to Uranium Miners. (Contract—Colorado State University.)

Studies to determine human health effects.

Funding level: $29,140.

Project description: This research was initiated as part of an integrated program to determine the effects of inhalation of radon and its daughters upon the induction of bronchogenic carcinoma in uranium miners. Forty actively working uranium miners were selected from two mines on the Colorado plateau along with ten control subjects residing in the area who had no known occupational exposure to radon progeny or mine environments. The miners were equipped with personal dosimeters consisting of a battery-operated air sampling pump and a thermoluminescent dosimeter (TLD) worn on the miner's hat and designed to sample and measure the radioactivity in the air which the miner actually breathed. Blood and whisker samples were collected on a regular basis for measurement of polonium-210 and lead-210 to determine the correlation between the measured Working Level Month (WLM) exposures to radon progeny and the subsequent deposition of long-lived radioactive decay products in the whiskers. The objective was to develop a reliable personal dosimeter and a reliable bioassay procedure that would indicate cumulative exposures over definite time periods.

Ionizing Radiation—Project I5–69

Project title: Studies of Uranium Miner Hazards Associated with Radon. (Contract—University of Rochester School of Medicine.)

Studies to determine human health effects.

Funding level: $119,000

Project description: In five separate but closely interrelated projects, senior scientists are conducting the following studies:

Project A—Effects on Dogs of Radon Decay Products (Donald Morken).

Project B–1—Measurement of ^{210}Pb Effective Half-Life in Dogs (John Hursh).

Project B–2—The Transport of ^{212}Pb from the Lung in Man (John Hursh).

Project C—Research on Attachment of Radon Decay Projects to Airborne Particles (T.T. Mercer).

Project D—Methods for Improved Bioassay of ^{210}Pb Body Burdens by Determination of ^{210}Pb and ^{210}Po in Urine and Feces (W.F. Bale and R.W. Helmkamp).

Project E—A Study of Quantitation Relationships Between Exposure to Radon and Radon daughters, as deduced from Exposure History and Various Experimentally Measured Parameters, and the Probability of Lung Cancer Development in Man and Experimental Animals (H.A. Blair).

PROJECT DESCRIPTIONS—FISCAL YEAR 1970

IONIZING AND NONIONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–70

Project title: "Respiratory Tract Dose Model for Uranium Miners."

Studies to determine human health effects.

Total man-years: 0.9. Funding level: $39,600.

Project description: The objective of this project is to develop a respiratory tract dose model that will provide reliable estimates of the dose of radiation to the basal cells of the bronchial epithelium of the respiratory tract in the case of inhalation of alpha emitters. The ideal method would be to calculate the dose to the basal cells in each anatomical region of the respiratory tract. This method requires a detailed description of the exposure atmosphere, a detailed respiratory tract model, accurate techniques of deposition calculation and an accurate analysis of the effects of clearance.

Ionizing Radiation—Project I2–70

Project title: "Energy Loss Characteristics of Radiation in Matter."

Studies to determine human health effects.

Total man years: 0.6. Funding level: $26,400.

Project description: The objectives of this project are to obtain more information on the main interactions of ionizing radiation with matter, such as ionization and excitation with molecules, such as the effect of the penetrating radiation upon molecular bonds. Such information will be basic to further analysis of the connections between physical energy loss and absorption processes and biological effects.

Ionizing Radiation—Project I3–70

Project title: "Interagency Review of the Health Hazards of Uranium Mining—Comparison of Experimental to Empirical Results."

Collection and/or analysis of health data.

Total man-years: 0.3. Funding level: $13,200.

Project description: This project is part of a Federal, Interagency Review of the health hazards of uranium mining. Scientists from all the federal agencies are participating in providing information for the review and in reviewing the total body of information available on radiogenic lung cancer. The sub-group dealing with radiogenic lung cancer has identified responsible agencies and due dates for the various parts of the review. The NIEHS is the responsible agency for a comparison of empirical and experimental information on radiogenic lung cancer.

Ionizing Radiation—Project I4–70

Project title: Research on the "Combined Effects of Inhalation of Uranium Ore Dust and Radon Daughters with Cigarette Smoke or Diesel Exhaust Fumes on the Lungs of Dogs and Hamsters." (Contract—Battelle Northwest-Pacific Northwest Laboratory.)

Studies to determine human health effects.

Funding level: $276,810.

Project description: As a major part of na integrated research program on the effects of exposure to radon and daughters on the development of lung cancer in uranium miners, the following animal studies were initiated:

1. Groups of hamsters are to be exposed to the following combinations: (*a*) Radon daughters on room air nuclei; (*b*) radon daughters and carnotite ore dust; (*c*) diesel engine exhaust alone; and (*d*) diesel exhaust fumes, radon daughters, and ore dust.

Analysis and control of concentrations of radon and daughters, composition of ore dust, and concentrations of other toxic agents in the diesel oil exhaust fumes will be made by the most advanced techniques available. After being exposed to alpha particles irradiation to predetermined cumulative dosage levels comparable to the WLM exposures of high-level exposed miners, the animals will be maintained for life for the observation of pathological changes, particularly lung cancer.

2. To test specifically the possible synergistic effects of radon and daughters and cigarette smoking, studies were initiated on three groups of 18 dogs as described below:

(*a*) Dogs exposed to radon daughters on carnotite ore—exposure for 4 hours per day, 7 days per week at concentrations of 15 nanocuries per liter.

(*b*) Dogs exposed to radon plus daughters on ore as in (*a*), plus two working shifts of smoking (total of 10 cigarettes per day with resting on alternate hours).

(*c*) Two shifts of smoking only, 10 cigarettes per day as in (*b*).

Regular clinical, radiological, radiographic, and hematological examinations will be made during and after the smoking and radon exposures. The dogs, except for one in each group to be sacrified for early histopathological studies, will be held for their remaining life span with observations of pulmonary changes and lung cancer as the end point.

Ionizing Radiation—Project I5–70

Project title: "Radon Progeny Inhalation Exposures to Uranium Miners." (Contract—Colorado State University.)

Studies to determine human health effects.

Funding level: $30,010.

Project description: This research was initiated as part of an integrated program to determine the effects of inhalation of radon and its daughters upon the induction of bronchogenic carcinoma in uranium miners. Forty actively working uranium miners were selected from two mines on the Colorado plateau along with ten control subjects residing in the area who had no known occupational exposure to radon progeny or mine environments. The miners were equipped with personal dosimeters consisting of a battery-operated air sampling pump and a thermoluminescent dosimeter (TLD) worn on the miner's hat and designed to sample and measure the radioactivity in the air which the miner actually breathed. Blood and whisker samples were collected on a regular basis for measurement of polonium-210 and lead-210 to determine the correlation between the measured Working Level Month (WLM) exposure to radon progeny and the subsequent deposition of long-lived radioactive decay products in the whiskers. The objective was to develop a reliable personal dosimeter and a reliable bioassay procedure that would indicate cumulative exposures over definite time periods.

Ionizing Radiation—Project I6–70

Project title: "Uranium Mining—Health Hazards Associated with Radon Daughters." (Contract—University of Rochester School of Medicine.)

Studies to determine the human health effects.

Funding level: $119,000.

Project description: In five separate but closely interrelated projects, senior scientists are conducting the following studies:

Project A—Dr. Donald Morken is exposing dogs to radon and radon daughters on room air nuclei. The magnitude and intensity of exposure versus early histopathological effects are important initially.

Project B—Dr. John Hursh is studying the bone and tissue distribution of ^{210}Pb as well as excretion of ^{210}Pb and ^{210}Po using dogs exposed in Project A.

Project B–2—Dr. Hursh has measured the transport time of ^{212}Pb from human lungs.

Project C—Dr. Thomas Mercer is studying the attachment of radon decay product atoms to particles and assists Hursh and Morken in characterizing the radon daughters carrying aerosols.

Project D—Dr. R. W. Helmkamp and Dr. W. F. Bale are developing new techniques for the measurement of ^{210}Po and ^{210}Pb in urine.

Project E—Dr. H. A. Blair is conducting a theoretical study of initiating doses and latent periods for the induction of lung cancer in uranium miners.

Nonionizing Radiation (Microwaves)—Project N1–70

Project title: "Microwave Exposure System and Microwave Dosimetry."

Studies to determine human health effects.

Total man-year: 0.60. Funding level: $26,400.

Project description: The objectives of this project are to develop a microwave exposure system for biological material which has a well-defined, uniform field characteristic, to study the mechanism of interaction of microwave radiation with matter, and to develop dosimetric relationships for energy absorption. A thorough study of the research requirements on the biological effects of microwaves was completed. Based on these studies, a set of specifications was written for a microwave field in a small laboratory space. At present, it is difficult to accurately measure low-level microwave fields and to determine the mechanisms by which the fields interact with matter. It is necessary, therefore, to conduct dosimetric studies so as to develop analytical interaction models. Microcalorimetry, thermoluminescence, chemical recations, liquid crystals, and photographic film are some of the techniques which will be investigated.

PROJECT DESCRIPTIONS—FISCAL YEAR 1971

IONIZING AND NONIONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–71

Project title: "Respiratory Tract Dose Model for Uranium Miners."

Study to determine human health effects.

Total man-years: 1.2. Funding level: $52,800.

Project description: The objective of this project is to develop a respiratory tract dose model that will provide reliable estimates of the dose of radiation to the basal cells of the bronchial epithelium of the respiratory tract in the case of inhalation of alpha emitters. Calculation of the dose to the basal cells in each anatomical region of the respiratory tract requires a detailed description of the exposure atmosphere, a detailed respiratory tract model, accurate techniques of depositions calculation and an accurate analysis of the effects of clearance.

Ionizing Radiation—Project I2–71

Project title: "Energy Loss Characteristics of Radiation in Matter."

Study to determine human health effects.

Total man-years: Funding level: $44,000.

Project description: The objectives of this project are to obtain more information on the main interactions of ionizing radiation with matter, such as ionization and excitation of atoms and molecules, and the more subtle interaction of radiation with molecules, such as the effect of the penetrating radiation upon molecular bonds. Such information will be basic to further analysis of the connections between physical energy loss and absorption processes and biological effects. The measurement of the energy loss of radiation is accomplished by using a solid state radiation spectrometer. The complete spectrometer consists of a measurement chamber containing an alpha, beta or gamma radiation source, multiple samples of the material to be studies and a solid state radiation detector. The doses and dose rates of alpha, beta and gamma radiation can be varied at will by adjusting the source-absorber geometry; and the solid state spectrometer allows an accurate determination of the energy loss in the absorber at the same time. This provides an experimental check on theoretical dose estimation. Biological absorbers can be studied with this system.

Ionizing Radiation—Project I3–71

Project title: "Interagency Review of the Health Hazards of Uranium Mining—comparison of Experimental to Empirical Results."

Collection and/or analysis of health data.

Total man-years: 0.5. Funding level: $22,000.

Project description: This project is part of a Federal Interagency Review of the health hazards of uranium mining. Scientists from all the federal agencies are participating in providing information for the review and in reviewing the total body of information available on radiogenic lung cancer. The subgroup dealing with radiogenic lung cancer has identified responsible agencies and due dates for the various parts of the review. The NIEHS is the responsible agency for a comparison of empirical and experimental information on radiogenic lung cancer. The epidemiological studies and toxicological studies were reviewed by other agencies. With their reviews as back-up information, the NIEHS reviewed the theoretical dose calculations and the relationship between the dose calculations and the epidemiological and toxicological results.

Ionizing Radiation—Project I4–71.

Project title: Research on the "Combined Effects of Inhalation of Uranium Ore Dust and Radon Daughters with Cigarette Smoke or Diesel Exhaust Fumes on the Lungs of Dogs and Hamsters." (Contract—Battelle Northwest-Pacific Northwest Laboratory.)

Studies to determine human health effects.

Funding level: $331,795,

Project description: As a major part of an integrated research program on the effects of exposure to radon and daughters on the development of lung cancer in uranium miners, the following animal studies were initiated:

1. Groups of hamsters are to be exposed to the following combinations: (A) Radon daughters on room air nuclei, (B) radon daughters on carnotite ore dust plus diesel exhaust fumes, and (C) diesel and exhaust fumes alone.

Analysis and control of concentrations of radon and daughters, composition of ore dust, and concentrations of other toxic agents in the diesel oil exhaust fumes will be made by the most advanced techniques available. After being exposed to alpha particle irradiation to predetermined cumulative dosage levels comparable to the WLM exposures of high-level exposed miners, the animals will be maintained for life for the observation of pathological changes, particularly lung cancer.

2. The test specifically the possible synergistic effects of radon and daughters and cigarette smoking, studies were initiated on three groups of 18 dogs as described below:

(a) Dogs exposed to radon and daughters on carnotic ore—exposure for 4 hours per day, 7 days per week at concentrations of 15 nanocuries per liter;

(b) Dogs exposed to radon plus daughters on ore as in (a), plus two working shifts of smoking (total of 10 cigarettes per day with resting on alternate hours);

(c) Two shifts of smoking only, 10 cigarettes per day as in (b).

Regular clinical, radiological, radiographic, and hematological examinations will be made during and after the smoking and radon exposures. The dogs, except for one in each group to be sacrificed for early histopathological studies, will be held for their remaining life span with observations of pulmonary changes and lung cancer as the end point.

Ionizing Radiation—Project I5–71

Project title: Radon Progeny Inhalation Exposures to Uranium Miners. (Contract—Colorado State University.)

Studies to determine human health effects.

Funding level: $30,010.

Project description: This research was initiated as part of an integrated program to determine the effects of inhalation of radon and its daughters upon the induction of bronchogenic carcinoma in uranium miners. Forty actively working uranium miners were selected from two mines on the Colorado plateau along with ten control subjects residing in the area who had no known occupational exposure to radon progeny or mine environments. The miners were equipped with personal dosimeters consisting of a battery-operated air sampling pump and a thermoluminescent dosimeter (TLD) worn on the miner's hat and designed to sample and measure the radioactivity in the air which the miner actually breathed. Blood and whisker samples were collected on a regular basis for measurement of polonium-210 and lead-210 to determine the correlation between the measured Working Level Month (WLM) exposures to radon progeny and the subsequent deposition and long-lived radioactive decay products in the whiskers. The objective was to develop a reliable personal dosimeter and a reliable bioassay procedure that would indicate cumulative exposures over definite time periods.

Ionizing Radiation—Project I6–71

Project title: "Uranium Mining—Health Hazards Associated with Radon Daughters." (Contract—University of Rochester School of Medicine.)

Studies to determine human health effects.

Funding level: $119,000.

Project description: In five separate but closely interrelated projects, senior scientists are conducting the following studies:

Project A—Dr. Donald Morken has exposed dogs to radon and radon daughters on room air nuclei. The magnitude and intensity of exposure versus early histopathological effects are important initially.

Project B–1—Dr. John Hursh is studying the bone and tissue distribution of ^{210}Pb as well as excretion of ^{210}Pb and ^{210}Po using dogs exposed in Project A.

Project B–2—Dr. Hursh has measured the transport time of ^{212}Pb from human lungs.

Project C—Dr. Thomas Mercer has characterized the radon daughter carrying aerosols used in the studies by Morken and Hursh.

Project D—Dr. R. W. Helmkamp and Dr. W. F. Bale developed new techniques for the measurement of ^{210}Po and ^{210}Pb in urine.

Nonionizing Radiation (microwaves)—N1–71

Project title: "Microwave Absorption by Biological Material."

Studies to determine human health effects.

Total man-years: 0.5. Funding level: $22,000.

Project description: The objectives of this project are to determine the absorption of microwave radiation by biological material, to investigate the contribution of cell structure to the absorption, and to attempt to explain the mechanism of interaction between microwaves and the biological material. DNA, RNA, protein, cell cultures and biologically simulated material (alcohol-water solutions) will be exposed to 2450 MHz microwave radiation. The amount of energy absorption will be measured, and the changes in the media will be evaluated with the assistance of the Cell Biology Branch.

Nonionizing radiation (microwaves)—N2–71

Project title: "Microwave Exposure System and Microwave Dosimetry."

Studies to determine human health effects.

Total man-years: 1. Funding level: $44,000.

Project description: The objectives of this project are to develop a microwave exposure system for biological material which has a well-defined, uniform field characteristic; to study the mechanisms of interaction of microwave radiation with matter; and to develop dosimetric relationships for energy absorption. A thorough study of the research requirements on the biological effects of microwaves was completed. Based on these studies, a set of specifications was written for a microwave exposure system which would generate a uniform, low-level microwave field in a small laboratory space. At present, it is difficult to accurately measure low level microwave fields and to determine the mechanisms by which the fields interact with matter. It is necessary, therefore, to conduct dosimetric studies so as to develop analytical interaction models. Microcalorimetry, thermister and thermocouple detectors, chemical reactions, liquid crystals, and photographic film are some of the techniques which will be investigated.

Nonionizing Radiation (microwaves)—N3–71

Project title: "Variable Frequency Microwave Exposure System."

Other studies: Biological effects are frequency dependent and variable frequency exposure systems are required for biological effects studies.

Total man-years: 0.20. Funding level: $8,800.

Project description: The objective of this project is to design, build, and calibrate a variable frequency exposure system for biological material. Specifications were written for the desired system. A field uniformity at the specimen of 90 percent over a 4 inch diameter circle, a continuous frequency variation in the range of 1 to 10 GHz, and a power level range at the specimen of 0.010 to 10 mM/cm^2 were specified. A complete search of the available microwave components was performed and from these components a system designed. Components for the system are now being ordered.

PROJECT DESCRIPTIONS—FY 1972

IONIZING AND NON-IONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–72

Project title: "Energy Loss Characteristics of Radiation in Matter."

Study to determine human health effects.

Total man-years: 1.2. Funding level: $52,000.

Project description: The objectives of this project are to obtain more information on the main interactions of ionizing radiation with matters, such as ionization and excitation of atoms and molecules, and the more subtle interactions of radiation with molecules, such as the effect of the penetrating radiation upon molecular bonds. Such information will be basic to further analysis of the connection between physical energy loss and absorption processes and biological effects.

Ionizing Radiation—Project I2–72

Project title: "Respiratory Tract Dose Model for Uranium Miners."

Study to determine human health effects.

Total man-years: 1.2. Funding level: $52,800.

Project description: The objective of this project is to develop a respiratory tract dose model that will provide reliable estimates of the dose of radiation to the basal cells of the bronchial epithelium of the respiratory tract in the case of inhalation of alpha emitters. Calculation of the dose to the basal cells in each anatomical region of the respiratory tract requires a detailed description of the exposure atmosphere, a detailed respiratory tract model, accurate techniques of deposition calculation and an accurate analysis of the effects of clearance.

Ionizing Radiation—Project I3–72

Project title: "Uranium Mining—Health Hazards Associated with Radon Daughters." (Contract—University of Rochester School of Medicine.)

Studies to determine the human health effects.

Funding level: $119,000.

Projection description: In five separate but closely interrelated projects, senior scientists have and/or are conducting the following studies:

Project A—Dr. Donald Morken has exposed dogs to radon and radon daughters on room air nuclei. The magnitude and intensity of exposure versus early histopathological effects are important initially.

Project B–1—Dr. John Hursh has studied the bone and tissue distribution of ^{210} Pb as well as excretion of ^{210}Pb and ^{210}Po using dogs exposed in Project A.

Project B–2—Dr. Hursh has measured the transport time of ^{212}Pb from human lungs.

Project C—Dr. Thomas Mercer has characterized the radon daughter carrying aerosols used in the studies by Morken and Hursh.

Project D—Dr. R. W. Helmkamp and Dr. W. F. Bale have developed new techniques for the measurement of ^{210}Po and ^{210}Pb in urine.

Ionizing Radiation—Project I4–72

Project title: Research on the "Combined Effects of Inhalation of Uranium Ore Dust and Radon Daughters with Cigarette Smoke of Diesel Exhaust Fumes on the Lungs of Dogs and Hamsters." (Contract—Battelle Northwest-Pacific Northwest Laboratory.)

Study to determine the human health effects.

Funding level: $331,795.

Project description: As a major part of an integrated research program on the effects of exposure to radon and daughters on the development of lung cancer in uranium miners, the following animal studies were initiated:

1. Groups of hamsters were exposed to the following combinations:

(*a*) radon daughters on room air nuclei; (*b*) radon daughters and carnotite ore dust; (*c*) diesel engine exhaust alone; (*d*) diesel exhaust fumes, radon daughters and ore dust; and (*e*) carnotite ore dust.

Concentrations of radon and daughters, composition of ore dust and concentrations of other toxic agents in the diesel oil exhaust fumes were carefully controlled. After being exposed to predetermined cumulative dosage levels comparable to the WLM exposures of high-level exposed miners, the animals were maintained for life for the observation of pathological changes, particularly lung cancer.

2. To test specifically the possible synergistic effects of radon and daughters and cigarette smoking, studies were initiated on three groups of 18 dogs as described below:

(*a*) Dogs exposed to radon and daughters on carnotite ore—exposure for 4 hours per day, 7 days per week at concentrations of 15 nanocuries per liter; with sham smoking;

(*b*) Dogs exposed to radon plus daughters on ore as in (*a*), plus two working shifts of smoking (total of 10 cigarettes per day with resting on alternate hours);

Regular clinical, radiological and radiographic examinations will be made ruring and after smoking and radon exposures. The dogs, except for one in each group which will be sacrificed for early histopathological studies, will be held for their remaining life span with observations of pulmonary changes and lung cancer as the end point.

Non-ionizing Radiation (Microwaves)—Project N1–72

Project title: "Variable Frequency Microwave Exposure System."

Other studies: Biological effects are frequency dependent and variable frequency exposure systems are required for biological effects studies.

Total man-years: 0.20. Funding level: $8,800.

Project description: The objective of this project is to design, build and calibrate a variable frequency exposure system for biological material. Specifications were written for the desired system. A field uniformity at the specimen of 90 percent over a 4-inch diameter circle, a continuous frequency variation in the range of 1 to 10 GHz and a power level range at the specimen of 0.010 to 10 mW/cm^2 were specified.

Nonionizing Radiation (microwaves)—Project N2–72

Project title: "Microwave Exposure System and Microwave Dosimetry."
Studies to determine human health effects.
Total man-years: 1. Funding level: $44,000.

Project description: The objectives of this project are to develop a microwave exposure system for biological material which has a well-defined, uniform field characteristic, to study the mechanism of interaction of microwave radiation with matter, and to develop dosimetric relationships for energy absorption. A thorough study of the research requirements on the biological effects of microwaves was completed. Based on these studies, a set of specifications was written for a microwave field in a small laboratory space. At present, it is difficult to accurately measure low-level microwave fields and to determine the mechanisms by which the fields interact with matter. It is necessary, therefore, to conduct dosimetric studies so as to develop analytical interaction models. Microcalorimetry, thermoluminescence, chemical reactions, liquid crystals, and photographic film are some of the techniques which will be investigated.

Nonionizing Radiation (microwave)—Project N3–72

Project title: "Microwave Absorption by Biological Material."
Studies to determine human health effects.
Total man-years: 1. Funding level: $44,000.

Project description. The objectives of this project are to determine the absorption of microwave radiation by biological material, to investigate the contribution of cell structure to the absorption and to attempt to explain the mechanism of interaction between microwaves and the biological material. DNA, RNA, protein cell cultures and biologically simulated material (alcohol-water solutions) will be exposed to 2450 MHz microwave radiation. The amount of energy absorption will be measured, and the changes in the media will be evaluated.

Nonionizing Radiation—Project N4–72

Project title: "Effects of 2450 MHz Microwave Radiation on Biological Material."
Studies ~~to determine~~ human health effects.
Total man-years: 1.2. Funding level: $52,800.

Project description: The objectives of this project are to determine how 2450 MHz microwave radiation interacts with biological material, to observe any effects of this interaction and to relate the amount of microwave energy absorbed to the effects. Several strains of bacteria and one bacteriophage have been exposed to 2450 MHz microwaves at power levels sufficient to maintain a temperature of 37°C. Growth rate curves and bacteriophage lysis time have been compared in exposed and control situations. DNA, other cell components and tissue culture cells may be exposed and studied later.

Nonionizing Radiation (microwave)—Project N5–72

Project title: "Investigation of Microwave Radiation on Neurological Functioning."
Studies to determine human health effects.
Total man-years: 0.1. Funding level: $4,400.

Project description: The project objective is an attempt to determining more fundamental reasons and mechanisms underlying the neurological effects of microwaves by studying the effects on basic neural structures. The hazards of microwave radiation are a priority matter of current concern for NIEHS. The study of biological effects caused by microwave radiation forms the basis for determining safe levels of exposures. Presently, the safe level of continuous exposure in the U.S.A. is 10 mW/cm^2. This is based on one underlying assumption: namely, that the possible damage due to microwave radiation exposure is of a thermal nature. However, many other experiments, especially from Soviet-block nations, report indications of nonthermal, neurological effects like headaches, fatigue, hyperactivity, altered brain wave patterns and changes in the functional state of nerves, e.g., induced transmembrane potentials. These observations occurred at radiation levels below the extant U.S.A. safe levels. The question of the nonthermal influence of microwaves is the principal one in the problems and consequences of the biological effects of microwaves, and it must be resolved before the degree of the hazard posed to man is determined.

Nonionizing Radiation (microwaves)—Project N6–72

Project title: "Study of Microwave Dosimetry" (Contract—University of Michigan).

Studies to determine human health effects.

Funding level: $51,525.

Project description: The objective of the contract is to develop techniques and detectors which can be used to measure the energy absorbed in a biological specimen placed in either the near or far microwave fields of frequencies ranging from 1 to 10 GHz. Small magnetic field probes have been built and calibrated in free space. These probes respond to the intensity of the magnetic field of the electromagnetic wave. Problems have been encountered in calibrating the probes in high dielectric constant materials and at high frequencies. These difficulties are due to the moding of the electromagnetic field in these materials. Therefore, the field in which the probe is placed is not well known. A technique for extrapolating the results to higher dielectric constant materials and higher frequencies has been theorized and will be applied in future work.

PROJECT DESCRIPTIONS—FISCAL YEAR 1973

IONIZING AND NONIONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–73

Project title: "Energy Loss Characteristics of Radiation in Matter."

Study to determine human health effects.

Total man-years: 1.5. Funding level: $66,000.

Project description: The objectives of this project are to obtain more information on the main interactions of ionizing radiation with matters, such as ionization and excitation of atoms and molecules, and the more subtle interactions of radiation with molecules, such as the effect of the penetrating radiation upon molecular bonds. Such information will be basic to further analysis of the connection between physical energy loss and absorption processes and biological effects. The measurement of the energy loss of radiation is accomplished by using a solid state radiation spectrometer. The complete spectrometer consists of a measurement chamber containing an alpha, beta or gamma radiation source, multiple samples of the material to be studied and a solid state radiation detector. The doses and dose rates of alpha, beta and gamma radiation can be varied at will by adjusting the source-absorber geometry; and the solid state spectrometer allows an accurate determination of the energy loss in the absorber at the same time. This provides an experimental check on theoretical dose estimation. Biological absorbers can be studied with this system.

Ionizing Radiation—Project I2–73

Project title: "Respiratory Tract Dose Model for Uranium Miners."

Study to determine human health effects.

Total man years: 1.4. Funding level: $61,600.

Project description: The objective of this project is to develop a respiratory tract dose model that will provide reliable estimates of the dose of radiation to the basal cells of the bronchial epithelium of the respiratory tract in the case of inhalation of alpha emitters. Calculation of the dose to the basal cells in each anatomical region of the respiratory tract requires a detailed description of the exposure atmosphere, a detailed respiratory tract model, accurate techniques of deposition calculation and an accurate analysis of the effects of clearance.

Ionizing Radiation—Project I3–73

Project title: "Study of the Combined Effects of Smoking and Inhalation of Uranium Ore Dust, Radon Daughters and Diesel Oil Exhaust Fumes in Hamsters and Dogs." (Contract—Battelle Northwest-Pacific Northwest Laboratory.)

Study to determine the human health effects.

Funding level: $336,000.

Project description: As a major part of an integrated research program on the effects of exposure to radon and daughters on the development of lung cancer in uranium miners, the following animal studies were initiated:

1. Groups of hamsters were exposed to the following combinations: (*a*) Radon daughters on room air nuclei; (*b*) radon daughters and carnotite ore dust; (*c*) diesel engine exhaust alone; (*d*) diesel exhaust fumes, radon daughters and ore dust; and (*e*) carnotite ore dust.

Concentrations of radon and daughters, composition of ore dust and concentrations of other toxic agents in the diesel oil exhaust fumes were carefully controlled. After being exposed to predetermined cumulative dosage levels, the animals were maintained for life for the observation of pathological changes, particularly lung cancer and emphysema.

2. To test specifically the possible synergistic effects of radon and daughters and cigarette smoking, studies were initiated on three groups of 18 dogs as described below:

(*a*) Dogs exposed to radon and daughters on carnotite ore—exposure for four hours per day, 7 days per week at concentrations of 15 nanocuries per liter; with sham smoking;

(*b*) Dogs exposed to radon plus daughters on ore as in (a), plus two working shifts of smoking (total of 10 cigarettes per day with resting on alternate hours);

Regular clinical, radiological and radiographic examinations will be made during and after smoking and radon exposures. The dogs, except for one in each group which will be sacrificed for early histopathological studies, will be held for their remaining life span with observations of pulmonary changes and lung cancer as the end point.

Nonionizing Radiation (microwaves)—Project N1–73

Project title: "Variable Frequency Microwave Exposure System."

Other studies: Biological effects are frequency dependent and variable frequency exposure systems are required for biological effects studies.

Total man-years: 0.20. Funding level: $8,800.

Project description: The objective of this project is to design, build, and calibrate a variable frequency exposure system for biological material. Specifications were written for the desired system. A field uniformity at the specimen of 90 percent over a 4 inch diameter circle, a continuous frequency variation in the range of 1 to 10 GHz, and a power level range at the specimen of 0.010 to 10 mW/cm^2 were specified. Many of the biological effects of microwave radiation are frequency dependent. In terms of whole body irradiation, a frequency of 150–1200 MHz affects the internal organs, whereas, a frequency of 10,000 MHz and above affects primarily the skin. Components of cells such as RNA, DNA and protein were found to have maximum absorption of different frequencies. Therefore, it is necessary to have the capability of varying frequency when investigating microwave effects on biological systems. The frequency range of 1 to 10 GHz was chosen because it is within this range of frequencies to which the general population is exposed.

Nonionizing Radiation (microwaves)—Project N2–73

Project title: "Microwave Exposure System and Microwave Dosimetry."

Studies to determine human health effects.

Total man-years: 1.5. Funding level: $66,000.

Project description: The objectives of this project are to develop a microwave exposure system for biological material which has a well-defined, uniform field characteristic, to study the mechanism of interaction of microwave radiation with matter, and to develop dosimetric relationships for energy absorption. A thorough study of the research requirements on the biological effects of microwaves was completed. Based on these studies, a set of specifications was written for a microwave field in a small laboratory space. At present, it is difficult to accurately measure low-level microwave fields and to determine the mechanisms by which the fields interact with matter. It is necessary, therefore, to conduct dosimetric studies so as to develop analytical interaction models. Microcalorimetry, thermoluminescence, chemical reactions, liquid crystals, and photographic film are some of the techniques which will be investigated.

Nonionizing Radiation (microwaves)—Project N3–73

Project title: "Effects of Microwave Radiation on the Embryonic Development of Japanese Quail."

Studies to determine human health effects.

Total man-years: 0.6. Funding level: $26,400.

Project description: The objective of this project is to determine the effects of microwave radiation on differentiating cells systems. Fertilized Japanese quail eggs will be exposed to microwave radiation in the frequency range of 1–10 GHz. The power level will initially be set to maintain a temperature of between 34° and 37° C in the quail egg. At these temperatures any effects due to the microwave radiation exposure should be nonthermal. If effects on cell differentiation is noted at those power density levels, the power level will be decreased until a threshold value is determined. The initial end point for observation of harmful effects will be deformities in the fully developed embryo.

Nonionizing Radiation (microwaves)—Project N4–73

Project title: "Investigation of Non-Thermal Microwave Radiation Effects on Neurological Functioning."

Studies to determine human health effects.

Total man-years: 0.75. Funding level: $33,000.

Project description: The objective of this project is to conduct an investigation into the non-thermal effects of microwave radiation on neurological functioning. The presently accepted working definition of a non-thermal effect is a biological change attributable to irradiation by microwave energy without significant change of body temperature. This definition does not exclude the possibility of specific local heating effects occurring even though there is no change of the overall or average temperature of the organism. To give a possible example for means of illustration: Conceivably, electric current flow in the cerebrospinal fluid could cause localized heating of the central nervous tissue. A change of temperature in the area of the hypothalamus amounting to not more than 0.1°C could provoke a generalized response of the antonomic nervous system. Such a response would be classed non-thermal inasmuch as it would not be a direct physical consequence of the energy input delivered by the irradiation.

Nonionizing Radiation (microwaves)—Project N5–73

Project title: "Effects of 2450 MHz Microwave Radiation on Biological Material."

Studies to determine human health effects.

Total man-years: 2.2. Funding level: $96,800.

Project description: The objectives of this project are to determine how 2450 MHz microwave radiation interacts with biological material, to observe any effects of this interaction and to relate the amount of microwave energy absorbed to the effects. Several strains of bacteria and one bacteriophage have been exposed to 2450 MHz microwaves at power levels sufficient to maintain a temperature of 37°C. Growth rate curves and bacteriophage lysis time have been compared in exposed and control situations. DNA, other cell components and tissue culture cells may be exposed and studied later.

Nonionizing Radiation (microwaves)—Project N6–73

Project title: "Study of Microwave Dosimetry." (Contract—Georgia Institute of Technology.)

Studies to determine human health effects.

Funding level: $33,155.

Project description: The objective of the contract is to develop techniques and detectors which can be used to measure the energy absorbed in a biological specimen placed either in the near or far microwave fields of frequencies ranging from 1 to 10 GHz. Georgia Institute of Technology has developed the technology to fabricate microwave detectors using a pyroelectric crystal (triglycine sulfate): A probe has been built and supplied to us which has good sensitivity at 4–10 GHz. Below 4–10 GHz it is necessary to add an absorbing material to the crystal to provide adequate sensitivity. The probe must be placed in a modulated field due to the fact that the probe measures a rate of change in temperature rather than an absolute temperature. Attempts to modulate the probe electronically rather than the incoming field has proved unfruitful. Also the miniaturization of the probe from the 0.5 cm × 0.5 cm has encountered difficulty. The sensitivity of the probe decreases rapidly with decreasing size.

Nonionizing Radiation (microwaves)—Project N7–73

Project title: "A Study of Microwave-Neuron Interaction." (Contract—Drake University.)

Studies to determine human health effects.

Funding level: $9,947.

Project description: The objective of this contract is to determine how microwave energy within the 0.1 to 3.0 GHz frequency range interacts with the human nervous system. There are two basic tasks being undertaken on this project: (*a*) Conduct studies aimed at determining the appropriate equivalent circuit of a neuron at microwave frequencies, and (*b*) develop instrumentation and measure induced transmembrane potential or any change in the firing pattern or activity of isolated nerve cells subjected to microwave irradiation.

PROJECT DESCRIPTIONS—FISCAL YEAR 1974

IONIZING AND NONIONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–74

Project title: "Theoretical Basis of Dose-Response Relationships."

Studies to determine human health effects.

Total man-years: 2. Funding level: $88,000.

Project description: The objective of this project is to develop a mathematical-theoretical model of the effects of ionizing radiation at the cellular level. Experimental and theoretical approaches are being developed. Experimental systems incorporating spectrometry systems have designed to facilitate the delivery of measured doses of alpha, beta or gamma radiation to cell cultures. A theoretical treatment, built upon data from the literature, is being used to focus the experimental work and to speculate on the nature of dose-response relationships under low-dose, low-dose rate conditions.

Ionizing Radiation—Project I2–74

Project title: "Study of the Combined Effects of Smoking and Inhalation of Uranium Ore Dust, Radon Daughters and Diesel Oil Exhaust Fumes in Hamsters and Dogs." (Contract—Battelle Northwest-Pacific Northwest Laboratory.)

Study to determine the human health effects.

Funding level: $325,000.

Project description: As a major part of an integrated research program on the effects of exposure to radon and daughters on the development of lung cancer in uranium miners, the following animal studies were initiated:

1. Groups of hamsters were exposed to the following combinations: (*a*) Radon daughters on room air nuclei; (*b*) radon daughters and carnotite ore dust; (*c*) diesel engine exhaust alone; (*d*) diesel exhaust fumes, radon daughters and ore dust; and (*e*) carnotite ore dust.

Concentrations of radon and daughters, composition of ore dust and concentrations of other toxic agents in the diesel oil exhaust fumes were carefully controlled. After being exposed to predetermined cumulative dosage levels, the animals were maintained for life for the observation of pathological changes, particularly lung cancer and emphysema.

2. To test specifically the possible synergistic effects of radon and daughters and cigarette smoking, studies were initiated on three groups of 18 dogs as described below:

a. Dogs exposed to radon and daughters on carnotite ore—exposure for 4 hours per day, 7 days per week at concentrations of 15 nanocries per liter; with sham smoking;

b. Dogs exposed to radon plus daughters on ore as in (a), plus two working shifts of smoking (total of 10 cigarettes per day with resting on alternate hours);

Regular clinical, radiological and radiographic examinations will be made during and after smoking and radon exposures. The dogs, except for one in each group which will be sacrificed for early histopathological studies, will be held for their remaining life span with observations of pulmonary changes and lung cancer as the end point.

Nonionizing Radiation (microwaves)—Project N1–74

Project title: "Microwave Exposure System and Microwave Dosimetry."

Studies to determine human health effects.

Total man-years: 2.2. Funding level: $96,800.

Project description: The objectives of this project are to develop microwave exposure systems for biological material which have well-defined, uniform field characteristics, and to develop dosimetric relationships for energy absorption. A thorough study of the research requirements on the biological effects of microwaves was completed. Based on these studies, a set of specifications was written for a microwave field in a small laboratory space. At present, it is difficult to accurately measure low-level microwave fields and to determine the mechanisms by which the fields interact with matter. It is necessary, therefore, to conduct dosimetric studies so as to develop analytical interaction models. Microcalorimetry, thermistor and thermocouple detectors, chemical reactions, liquid crystals, and photographic film are some of the techniques which will be investigated.

Nonionizing Radiation (microwaves)—Project N2–74

Project title: "Effects of 2450 MHz CW Microwave Radiation on the Embryonic Development of Japanese Quail."

Studies to determine human health effects.

Total man-years: 1.2. Funding level: $52,800.

Project description: The objectives of this project are to determine the effects of 2450 MHz CW microwave radiation on the embryological development of Japanese quail. Fertilized Japanese quail eggs were exposed to 2450 MHz microwave radiation for four hours per day during the first five days of incubation. A power level ($30 mW/cm^2$) was chosen that would hold the temperature of the eggs at incubation temperature (35–37°C). The newly hatched quail were examined for changes in percent hatched, gross deformaties and several blood parameters. The blood parameters studied were hermatric hemoglobin, erythrocyte number and differential leucocyte percentages.

Non-ionizing radiation (microwaves)—Project N3–74

Project title: "Effects of 2450 MHz Microwave Radiation on Biological Material at Cellular and Macromolecular Level."

Studies to determine human health effects.

Total man-years: 0.8. Funding level: $35,200.

Project description: The objectives of this project are to determine how 2450 MHz microwave radiation interacts with biological material at the cellular and a macromolecular level, to observe any effects of this interaction and to relate the amount of microwave energy absorbed to the effects. Several strains of bacteria, one bacteriophage and solutions of DNA have been exposed to 2450 MHz microwaves at power levels sufficient to maintain a temperature of 37° C. Bacterial growth rate curves and bacteriophage lysis times have been compared in exposed and control situations. Thermal denaturation curves of control and exposed DNA solutions have been compared with the aid of an ultraviolet spectrophotometer equipped with a temperature programmer. Embryos from mice were exposed for 22 hours in test tubes at $100 mW/cm^2$ during the 2 to 4 cell stage and implanted in other mice for continued development. Washed rabbit erythrocytes have been exposed at several power levels and the cells examined for leakage of potassium and hemoglobin and changes in osmotic resistance.

Nonionizing Radiation (microwaves)—Project N4–74

Project title: "Effects of Microwave Radiation on the Neural Response."

Studies to determine human health effects.

Total man-years: 1.25. Funding level: $55,000.

Project description: The objective of this project is to determine the effects of microwave radiation on the functioning of the central nervous system when exposed to CW and modulated microwave radiation in the frequency range of 1–10 GHz. Isolated neurons such as the adominal ganglion of the *Aplysia*, the sciatic nerve of the frog, and the saphenous nerve of cats will be exposed to CW and modulated microwave radiation in the power density range of 1–10 mW/cm^2. The effects of the radiation on cell membrane potentials, action potential and conduction velocity will be investigated. More complex systems such as the exposed spinal cord of decerebrated cats will be exposed. These test systems will be used to investigate the effects of radiation on synaptic neurotransmitters.

Nonionizing Radiation (microwaves)—Project N5–74

Project title: "Development of Microwave Instrumentation." (Contract—Duke University.)

Studies to determine human health effects.

Funding level: $15,267.

Project description: The proposed work of this contract is threefold: (1) Study the electrical dipole model of the neural membrane and its implications, and to determine the unknown parameters in the interaction of the dipole model with microwave radiation; (2) Develop microwave instrumentation and methods to investigate microwave-neuron interactions over the 0.2 to 3 GHz frequency band; and (3) Develop the instrumentation and dosimetry of a more accurate method of determining the microwave power absorbed by a neuron.

PROJECT DESCRIPTIONS—FISCAL YEAR 1975

IONIZING AND NONIONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–75

Project title: "Theoretical Basis of Dose-Response Relationships."

Studies to determine human health effects.

Total man-years: 2.5. Funding level: $110,000.

Project description: The objective of this project is to develop a mathematical-theoretical model of the effects of ionizing radiation at the cellular level. Experimental and theoretical approaches are being developed. Experimental systems incorporating spectrometry systems have designed to facilitate the delivery of measured doses of alpha, beta or gamma radiation to cell cultures. A theoretical treatment, built upon data from the literature, can be used to focus the experimental work and to predict the nature of dose-response relationships under low-dose, low-dose rate conditions.

Ionizing Radiation—Project I2–75

Project title: "Study of the Combined Effects of Smoking and Inhalation of Uranium Ore Dust, Radon Daughters and Diesel Oil Exhaust Fumes in Hamsters and Dogs." (Contract—Battelle Northwest-Pacific Northwest Laboratory.)

Study to determine the human health effects.

Funding level: $200,000.

Project description: As a major part of an integrated research program on the effects of exposure to radon and daughters on the development of lung cancer in uranium miners, the following animal studies were initiated:

1. Groups of hamsters were exposed to the following combinations: (*a*) Radon daughters on room air nuclei; (*b*) Radon daughters and carnotite ore dust; (*c*) Diesel engine exhaust alone; (*d*) Diesel exhaust fumes, radon daughters and ore dust; and (*e*) Carnotite ore dust.

Concentrations of radon and daughters, composition of ore dust and concentrations of other toxic agents in the diesel oil exhaust fumes were carefully controlled. After being exposed to predetermined cumulative dosage levels, the animals were maintained for life for the observation of pathological changes, particularly lung cancer and emphysema.

2. To test specifically the possible synergistic effects of radon and daughters and cigarette smoking studies were initiated on three groups of 18 dogs as described below:

a. Dogs exposed to radon and daughters on carnotite ore—exposure for 4 hours per day, 7 days per week at concentrations of 15 nanocuries per liter; with sham smoking;

b. Dogs exposed to radon plus daughters on ore as in (a), plus two working shifts of smoking (total of 10 cigarettes per day wtih resting on alternate hours);

Regular clinical, radiological and radiographic examinations will be made during and after smoking and radon exposures. The dogs, except for one in each group which will be sacrificed for early histopathological studies, will be held for their remaining life span with observations of pulmonary changes and lung cancer as the end point.

Nonionizing Radiation (microwaves)—Project N1–75

Project title: "Microwave Exposure System and Microwave Dosimetry."

Studies to determine human health effects.

Total man-years :0.80. Funding level: $35,200.

Project description: The objectives of this project are to develop microwave exposure systems for biological material which have well-defined, uniform field characteristics, and to develop dosimetric relationships for energy absorption. A thorough study of the research requirements on the biological effects of microwaves was completed. Based on these studies, a set of specifications was written for a microwave field in a small laboratory space. At present, it is difficult to accurately measure low-level microwave fields and to determine the mechanisms by which the fields interact with matter. It is necessary, therefore, to conduct dosimetric studies so as to develop analytical interaction models. Microcalorimetry, thermistor and thermocouple detectors, chemical reactions, liquid crystals, and infrared microscopes are some of the techniques which will be investigated. Other instruments for measuring incident and absorbed energy will be evaluated as they become available.

Nonionizing Radiation (microwaves)—Project N2–75

Project title: "Measurement of Energy Absorption from Microwave Fields."

Studies to determine human health effects.

Total man-years: 1.2. Funding level: $52,800,

Project description: Measurement of the absorption of microwave energy on the basis of fundamental physical laws. Microwaves are absorbed in a spherical shell of dielectric material enclosing a dry gas or a spherical shell of dry gas enclosing the dielectric. Temperature changes of the dielectric are transmitted to the gas which expands in accord with the ideal gas law over the range of pressure and temperatures encountered.

Nonionizing Radiation (microwaves)—Project N3–75

Project title: "Effects of 2450 MHz CW Microwave Radiation on the Embryonic Development of Japanese Quail."

Studies to determine human health effects.

Total man-years: 1.5. Funding level: $66,000.

Project description: The objectives of this project are to determine the effects of 2450 MHz CW microwave radiation on the embryological development of Japanese quail. Fertilized Japanese quail eggs were exposed to 2450 MHz microwave radiation at various times and durations during the incubation period. Temperature and humidity conditions are carefully controlled and may be varied to suit the experimental protocol. The newly hatched quail are examined for changes in percent hatched, gross deformities and several blood parameters. The blood parameters studied were hematocrit, hemoglobin, erythrocyte and leukocytes number and differential leukocyte percentages.

Nonionizing Radiation (microwaves)—Project N4–75

Project tile: "Effects of 2,450 MHz Microwave Radiation on Biological Materials at Cellular Level."

Studies to determine human health effects.

Total man-years: 1.1. Funding level: $48,400.

Project description: The objectives of this project are to determine how 2,450 MHz microwave radiation interacts with biological material at the cellular and macromolecular level, to observe any effects of this interaction and to relate the amount of microwave energy absorbed to the effects. Various cellular and macromolecular systems are exposed to microwave radiation at carefully controlled temperatures and exposure levels. Much of the work has been at 37°C. Some biological systems employed in the study are: bacteria and bacteriophage, solutions of DNA, 2–4 cell stage embryos from mice, rabbit erythrocytes and human mouse lymphocytes.

Nonionizing Radiation (microwaves)—Project N5–75

Project title: "Effects of Microwave Radiation on the Neural Response."

Studies to determine human health effects.

Total man-years: 0.25. Funding level: $11,000.

Project description: The objective of this project is to determine the effects of microwave radiation on the functioning of the central nervous system when exposed to CW and modulated microwave radiation in the frequency range of 1–10 GHz. Isolated neurons such as the adominal ganglion of the *Aplysia*, the sciatic nerve of the frog, and the saphenous nerve of cats will be exposed to CW and modulated microwave radiation in the power density range of 1–10 mW/cm^2. The effects of the radiation on cell membrane potentials, action potential and conduction velocity will be investigated. More complex systems such as the exposed spinal cord of decerebrated cats will be exposed. These test systems will be used to investigate the effects of radiation on synaptic neurotransmitters.

Nonionizing Radiation (microwaves)—Project N6–75

Project title: "Development of Microwave Instrumentation." (Contract—Duke University.)

Studies to determine human health effects.

Funding level: $15,267.

Project description: The proposed work of this contract is threefold: (1) Study the electrical dipole model of the neural membrane and its implications, and to determine the unknown parameters in the interaction of the dipole model with microwave radiation; (2) Develop microwave instrumentation and methods to investigate microwave-neuron interactions over the 0.2 to 3.0 GHz frequency band; and (3) Develop the instrumentation and dosimetry of a more accurate method of determining the microwave power absorbed by a neuron.

PROJECT DESCRIPTIONS—FISCAL YEAR 1976

IONIZING AND NONIONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–76

Project title: "Theoretical Basis of Dose-Response Relationships."

Studies to determine human health effects.

Total man-years: 2.9. Funding level: $127,600.

Project description: The objective is to examine whether generalized conceptual schemes can be proposed within which experimental and theoretical work can be directed to answer critical questions in dose-response analysis. This project has included the development of a generalized theoretical model for the effects of ionizing radiation at the cellular level. A three-state model at the cellular level (normal cells, killed cells, altered cells) appears to encompass existing data and existing models on the effects of ionizing radiation. Such a model can be used to focus experimental work which, in turn, will lead to further model development. Questions to be addressed are: (1) Whether, and at what level, models can incorporate effects of chemical, biological and physical agents;

(2) whether paradigms for extrapolation can be proposed; and (3) whether correspondence rules can be mechanistic (relate microevents to macroevents) or only phenomenological (macroevents only).

Nonionizing Radiation (microwaves)—Project N1–76

Project title: "Microwave Exposure System and Microwave Dosimetry."

Studies to determine human health effects.

Total man-years: 0.9. Funding level: $39,600.

Project description: The objectives of this project are to develop microwave exposure systems for biological material which have well-defined, uniform field characteristics, and to develop dosimetric relationships for energy absorption. A thorough study of the research requirements on the biological effects of and techniques for exposing biological specimens have been completed. Based on these studies, exposure systems will be designed and developed which provide known electromagnetic field characteristics. At present, it is difficult to accurately measure low level microwave fields and to determine the mechanisms by which the fields interact with matter. It is necessary, therefore, to conduct dosimetric studies so as to develop analytical interaction models. Microcalorimetry, thermistor and thermocouple detectors, chemical reactions, liquid crystals and photographic film are some of the techniques which will be investigated. Other techniques to determine energy absorption will be evaluated as they become available.

Nonionizing Radiation (microwaves)—Project N2–76

Project title: "Investigation of Microwave Radiation Effects on Neurological Functioning."

Studies to determine human health effects.

Total man-years: 0.5. Funding level: $22,000.

Project description: The objective of this project is to determine the effects of microwave radiation on the functioning of the central nervous system when exposed to CW and modulated microwave radiation in the frequency range of 1–10 GHz. Isolated neurons such as the abdominal ganglion of the *Aplysia*, the sciatic nerve of the frog, and the saphenous nerve of cats will be exposed to CW and modulated microwave radiation on cell membrane potentials, action potentials and conduction velocity will be investigated. More complex systems such as the exposed spinal cord of decerebrated cats will be exposed. These test systems will be used to investigate the effects of radiation on synaptic neurotransmitters.

Nonionizing Radiation (microwaves)—Project N3–76

Project title: "Effects of 2450 MHz Microwaves on Embryonic Development of Japanese Quail."

Studies to determine human health effects.

Total man-years: 1.3. Funding level: $57,200.

Project description: The objectives of this project are to determine the effects of 2450 MHz CW microwave radiation on the embryological development of Japanese quail and the subsequent growth, reproduction, and immunological response of the mature quail which had been exposed during the developmental period. Fertilized Japanese quail eggs were exposed to 2450 MHz CW microwave for various periods of embryonic development at power densities of 30 mW/cm^2 and 5 mW/cm^2. The effects of exposure on hatchability, gross deformities and hematological parameters were measured in the 2 day old quail. Fertilized eggs were also exposed to 5 mW/cm^2 for the first 12 days of development. The quail were kept to maturity and growth rates, egg production, fertility and immunological response were measured.

Nonionizing Radiation (microwaves)—Project N4–76

Project title: "Effects of 2450 MHz Microwave Radiation on Biological Materials at Cellular Level."

Studies to determine human health effects.

Total man-years: 1. Funding level: $44,000.

Project description: The objectives of this project are to determine how 2450 MHz microwave radiation interacts with biological material at the cellular and macromolecular level, to observe any effects of this interaction and to relate the amount of microwave energy absorbed to the effects. Various cellular and macromolecular systems are exposed to microwave radiation at carefully controlled temperatures and exposure levels. Much of the work has been at 37°C. Biological systems employed in the study are: bacteria and bacteriophage, solutions of DNA, 2–4 cell stage embryos from mice, rabbit erythrocytes and rat lymphocytes.

Nonionizing Radiation (Extra Low Frequency)—Project N5–76

Project title: "Effects of 60 Hz Fields on the Mammalian Central Nervous System." (Contract—University of California—Los Angeles.)

Studies to determines the human health effects.

Funding level: $99,994.

Project description: The objectives of this research are to determine the effects of 60 Hz fields from high voltage transmission lines on the central nervous system of mammals. Environmental field conditions similar to those found in the vicinity of high voltage transmission lines will be simulated. These field gradiants will range from 1 to 2000 volts/meter. The effects of these fields on the biological rhythms in rats and conditional behavior in monkeys will be evaluated. The effects on the neuroendocrine mechanism in rats and primates will be examined by using 17-hydroxysteroids, calcium, phosphorus, vanilmandelic acid and other urinary indicators of biorhythmicity. Changes in the neurochemistry of brain tissue of cats will be studied. These studies will include the measurement of both Ca and amino acid effluxes from the cerebral cortex of the cat.

PROJECT DESCRIPTIONS—FISCAL YEAR 1977

IONIZING AND NONIONIZING RADIATION

In-house and Contracts

Ionizing Radiation—Project I1–77

Project title: "Theoretical Basis of Dose Response Relationships."

Study to determine human health effects.

Total man-years: 0.2. Funding level: $880,000.

Project description: The purpose of this project is to continue development of theoretical models of dose-response relationships for ionizing radiation at the cellular level and to begin the development of generalized conceptual schemes encompassing chemical, biological and physical agents. The current approach is to: (1) Accumulate existing data for chemical, biological and physical agents on cell survival, mutagensis and carcinogenesis that is suitable for dose-response analysis; (2) selection of models that can be applied to the data base in (1); and (3) propose conceptual schemes within which further data can be accumulated to answer critical questions raised in (1) and (2).

Nonionizing Radiation (Microwaves)—Project N1–77

Project title: "Microwave Exposure System and Microwave Dosimetry."

Studies to determine human health effects.

Total man-years: 1.1. Funding level: $48,400.

Project description: The objectives of this project are to develop microwave exposure systems for biological material which have well-defined, field characteristics, and to develop dosimetric relationships for energy absorption. A thorough study of the research requirements on the biological effects of and techniques for exposing biological specimens have been completed. Based on these studies, exposure systems will be designed and developed which provide known electromagnetic field characteristics. At present, it is difficult to accurately measure low level microwave fields and to determine the mechanisms by which the fields interact with matter. It is necessary, therefore, to conduct dosimetric studies so as to develop analytical interaction models. Microcalorimetry, thermistor and thermocouple detectors, and liquid crystals are some of the techniques which will be investigated. Other techniques to determine energy absorption will be evaluated as they become available.

Nonionizing Radiation (Microwaves)—Project N2–77

Project title: "Effects of Microwaves on Neural Response."

Study to determine human health effects.

Total man-years: 0.8. Funding level: $35,200.

Project description: The objective of this project is to determine the effect of microwave radiation on neurological response. Isolated neurons such as the abdominal ganglion of the *Aplysia*, the sciatic nerves of frogs and the saphenous nerves of cats will be exposed to CW, pulsed and modulated microwave radiation in the power density range of 1–10 mW/cm^2. The effects of the microwave radiation on the strength-duration of a stimulus to produce an action potential, amplitude of the response, and conduction velocity will be investigated. The fatigue and recovery of the neurons under rapid, multiple stimulation will also be studied.

Nonionizing Radiation (microwaves)—Project N3–77

Project title: "Effects of 2450 MHz Microwave Radiation on Biological Materials at Cellular Level."

Studies to determine human health effects.

Total man-years: 1. Funding level: $44,000.

Project description: The objectives of this project are to determine how 2450 MHz microwave radiation interacts with biological material at the cellular and macromolecular level, to observe any effects of this interaction and to relate the amount of microwave energy absorbed to the effects. Biological systems employed in the study are: bacteria and bacteriophage, solutions of DNA, 2–4 cell stage embryos from mice, rabbit erythrocytes and rat lymphocytes. In these experiments, the temperature, humidity, and other various growth conditions have been carefully monitored in order to eliminate any effects not intrinsically caused by the microwave radiation.

Nonionizing Radiation (microwaves)—Project N4–77

Project title: "Effects of 2450 MHz Microwaves on Embryonic Development, Immunology and Fertility."

Study to determine human health effects.

Total man-years: 1.3. Funding level: $37,200.

Project description: The objectives of this project are to determine the effects of 2450 MHz CW microwave radiation on the embryological development of Japanese quail and the subsequent growth, reproduction, and immunological response of the mature quail which had been exposed during the developmental period. Fertilized Japanese quail eggs were exposed to 2450 MHz CW microwave for various periods of embryonic development at power densities of 30 mW/cm^2 and 5 mW/cm^2. The effects of exposure on hatchability, gross deformities and hematological parameters were measured in the 2 day old quail. Fertilized eggs were also exposed to 5 mW/cm^2 for the first 12 days of development. The quail were kept to maturity and growth, rates, egg production, fertility and immunological reponse were measured.

Nonionizing Radiation (microwaves)—Project N5–77

Project title: "Effects of Microwave Radiation on the Nervous System." (Contract—University of Washington.)

Study to determine human health effects.

Funding level: $129,867.

Project description: The objective of this project is to determine the effects of long-term, low-level, exposure to 918 and 2450 MHz microwave radiation on the central nervous system and behavior. Long-evans male rats, 80–90 days of age will be exposed to 915 and 2450 MHz circular polarized microwave radiation at a power density level such that the specified absorption rate will be equivalent to that produced in a 5 mW/cm^2 plane wave field. The exposure will be 8 hours a day, 7 days a week for 4 months. Two months postirradiation evaluations will be performed. Rats will also be exposed to 2450 MHz plane wave microwave field at a power density of 500 μW/cm^2 using the same schedule as that stated above. The following indicators of biological effects will be made:

1. Biochemistry—Serum content for sodium, calcium, phosphorus, PTH, SH groups and cholorinesterase activity of the blood and 17-ketosteroids in urine will be measured.
2. Behavior—Animals will be evaluated for free-operant and free-repertoire behavior. Animals will be observed in the irradiation chambers and their specific orientation to the field, sleep, grooming, sniffing, rearing, drinking, eating, etc., will be recorded.

3. Electroencephalography—EEG recordings will be made on the animals following the 4-month irradiation period.

In addition to the above endpoints, some behavioral teratology, cataract evaluation, and longevity data will be obtained.

Nonionizing Radiation (microwaves)—Project N6–77

Project title: "Effects of Microwave Radiation on the Nervous System." (Contract—University of Utah.)

Study to determine human health effects.

Funding level: $98,194.

Project description: The objective of this period is to determine the effects of long-term, low-level exposure to 915 and 2450 MHz microwave radiation on the central nervous system and behavior. Long Evans male rats will be exposed to a CW plane wave microwave field at frequencies of 915 to 2450 MHz and power density of 5 mW/cm^2. The animals will be exposed for 8 hours a day, 5 days a week for 16 weeks. An eight week recovery period will follow the exposure period. The following measurements will be made:

1. Biochemistry—Biochemical analysis of the cholinesterase activity of the blood, the SH group in the blood, and ketosteroids in the urine will be measured.
2. Behavior—Rodent activity will be measured using a rodent activity wheel. Water and food intake will be measured. Rats will be trained to lever press for food reward on a FR–DRL multiple schedule. Total response and reinforcement for each schedule component as well as response during time out between each component will be recorded.
3. EEG—EEG will be recorded biweekly using epidural removable stainless steel electrodes. These recordings will be made while the microwave radiation is turned off.

Nonionizing Radiation (Extra Low Frequency)—Project N7–77

Project title: "Effects of 60 Hz Fields on the Mammalian Central Nervous System." (Contract—University of California-Los Angeles.)

Studies to determine the human health effects.

Funding level: $99,994.

Project description: The objectives of this research are to determine the effects of 60 Hz fields from high voltage transmission lines on the central nervous system of mammals. Environmental field conditions similar to those found in the vicinity of high voltage transmission lines will be simulated. These field gradients will range from 1 to 2000 volts/meter. TITLE OF PROJECT
Human Radioactivity Dose Study

USE THIS SPACE TO ABSTRACT YOUR PROPOSED RESEARCH. OUTLINE OBJECTIVES AND METHODS. UNDERSCORE THE KEY WORD (NOT TO EXCEED 10) IN YOUR ABSTRACT.

Abstract - The purpose of this study is to provide detailed dose estimates to the critica cells in tumor formation from the important radionuclides expected to be prevalent in our environment within the next decade. Two groups of nuclides are to be studied, the alpha emitters which predominate in spent nuclear fuel, namely ^{238}Pu, ^{241}Pu, ^{241}Am, ^{242}Cm ^{244}Cm and the beta emitting fission product ^{85}Kr. Estimates are that by 1985 4×10^9 Curies of the transuranics will be reprocessed per year, while atmospheric ^{85}Kr levels could be as high as 10^4 pCi/m^3 by the turn of the century.

Release of transuranics to the environment can result in human exposures by ingestio or inhalation. Soluble forms of these nuclides are bone seekers and critical cells on bone surfaces are irradiated. Inhalation of less soluble particulates irradiates critical cells in the lower lung over long time intervals. Krypton-85 is very soluble in body fat and 13% of body storage fat is located in yellow bone marrow in bone shafts. It is thus capable of producing an important beta dose to bone cells adjacent to bone marrow as well as a dose to critical basal cells in bronchial epithelium upon inhalation.

There is no human experience with high levels of these emitters to indicate their absolute toxicity. Whether the exposure is from inhaled or ingested material, the distribution of the transuranic nuclides in the body is quite different from that of radium or radon daughter exposure where human data on tumor induction in bone and lung do exist. A key to evaluating the toxicity of these nuclides as well as ^{85}Kr lies in the estimation of the critical cell rad doses for their disposition in the body and compariso of this dose with those estimated where tumor induction in humans has occurred. In this proposal we show that this type of detailed dose estimate is now possible.

All of our dose estimates will be computed from measured energy loss data in tissue-like material. The measurement of beta energy loss will allow unique calculations since these data are not as yet available for accurate spatial dosimetry.

TITLE OF PROJECT

Environmental Factors Related to Chromosome Damage

USE THIS SPACE TO ABSTRACT YOUR PROPOSED RESEARCH. OUTLINE OBJECTIVES AND METHODS. UNDERSCORE THE KEY WORD (NOT TO EXCEED 10) IN YOUR ABSTRACT.

The goals of this study are 1) to determine what environmental factors are associated with "somatic mutations" as manifested in chromosome breakage and other evidence of chromosome damage which occurs in those with evidence of embryotoxicity and 2) to investigate the feasibility of a new method of evaluation of chromatid interchanges (using Hoechst 33258 binding) and its applicability to the determination of chromosome damage in the population under study; and, in so doing, to assess the more general applicability of this approach to the monitoring of populations "at risk" which are known to be exposed to possible environmental hazards such as X-irradiation, pesticides, etc. Chromatid interchanges as detected with this method will be correlated with the frequency of chromosome breakage in the population under study as well as with history of exposure to radiation, among other factors.

TITLE OF PROJECT The Nature of Radiation Induced Genetic Damage

USE THIS SPACE TO ABSTRACT YOUR PROPOSED RESEARCH. OUTLINE OBJECTIVES AND METHODS. UNDERSCORE THE KEY WORD (NOT TO EXCEED 10) IN YOUR ABSTRACT.

The relation between radiation-induced mutations and chromosome breaks is not understood at the present time; a new hypothesis of the whole animal from only one of the first two cleavage products appears to resolve some of the problems. The research will focus on the study of the production of mosaics in Drosophila melanogaster as a function both of X-ray dose and chemical treatment, and the computer analysis of genetic data on chromosome loss and dominant lethal production in view of this hypothesis.

GRANT NO. ES00002-14

NARRATIVE JUSTIFICATION OF FUNDS REQUESTED FOR RADIOBIOLOGY

PROGRAM:

The overall aim of this program is to learn more about the biologic effects of ionizing radiation, including particulary the effects of of alpha radiation in the lungs and the possible interactions of alpha-emitters and chemical carcinogens in malignant transformation and the production of lung tumors.

EQUIPMENT:

Walk-in Environmental Chamber

A cold room is needed for two reasons: First, the increased demand for tissue culture media has created an acute cold storage problem. Since media is prepared in bulk and must be stored 48 hours until sterility tests are completed, up to 100 liters must be stored in isolation at one time. The second reason is our work is leading toward enzymatic studies in which chromatography at 4°C is necessary. This will require at least a 6' x 6' cold area. The two requirements together make the acquisition of a cold room very important to our research program.

SUMMARY OF PROPOSED WORK – *(200 words or less – Omit Confidential data.)*

In the Science Information Exchange summaries of work in progress are exchanged with government and private agencies supporting research in the biosciences and are forwarded to investigators who request such information. Your summary is to be used for these purposes.

To evaluate the genetic hazard of chemicals in our environment and understar their mode of action it is necessary to place chemical mutagenesis on a quantitat basis in a eukaryote organism that can be thoroughly and economically analyzed genetically. Ethyl methanesulfonate (EMS) was selected as the mutagen for developing a model test system because of its known mutagenic effectiveness and i simple chemical structure which makes it relatively easy to synthesize with radionuclides having high specific activity. The mutagenic action of EMS is cons due to its alkylation of DNA, a point of view supported by previous work on this project using Drosophila in a bio-assay of blood plasma from hamsters that had be previously injected with EMS. To place the dosage of EMS on a quantitative basis alkylation of DNA in *Drosophila melanogaster* spermatozoa is measured on a per spe cell basis and then further divided into alkylation at specific sites such as th 7 position of guanine. This dosimetry will then permit the construction of dosag response curves with the dose in terms of alkylation and the response in terms of extensive mutational spectrum developed with Drosophila. This project differs fr previous work with alkylation in that we are studying both alkylation and the gene consequence within the same germinal tissue of a eukaryote. Results of these test would eventually enable us to determine whether, as the dose is reduced, repair mechanisms become sufficiently effective to reduce the mutational effect to no gre than the spontaneous rate or if there is a genetic hazard due to low level exposur to alkylating agents. This answer is basic to determining the genetic hazard of a constant low level mutagen in our environment. This work is being expanded to include the bisulfite ion, heavy metals and other environmental mutagens.

SUMMARY OF PROPOSED WORK — (200 words or less — Omit Confidential data.)

In the Science Information Exchange summaries of work in progress are exchanged with government and private agencies supporting research in the bio-sciences and are forwarded to investigators who request such information. Your summary is to be used for these purposes.

Previous research by the principal investigator has produced surprising results when X-irradiated insects were treated with insecticides. It is the purpose of this project to irradiate all stages of insect development at varying intervals and dosages before and after exposure to varying dosages of insecticides, and to determine the effects on their toxicity to these different stages. From these time, toxicant, and irradiation dosage variations the modes of toxic action will be explored more intricately through physiological studies. These will involve looking for cholinesterase and aliesterase changes, amino acid alterations, peroxide, fatty acid and free cation levels, both with regard to changes in the insect biochemistry resulting from the toxicant and irradiation.

Aside from the purely physiological aspects, we will also look for changes in development rate, body weight, general activity or behavior, feeding rates and longevity, all to be compared with the two control sets.

TITLE OF PROJECT

Research in the Environmental Health Sciences

USE THIS SPACE TO ABSTRACT YOUR PROPOSED RESEARCH. OUTLINE OBJECTIVES AND METHODS. UNDERSCORE THE KEY WOR (NOT TO EXCEED 10) IN YOUR ABSTRACT.

This grant provides core support for a broad program in the environmental health sciences. The research under way and proposed is broadly relevant to adverse health effects from environmental factors. The general objectives of the research are to define the nature and extent of such effects with the aim of instituting appropriate preventive or control procedures where required. Interests range from acute to chronic health effects including, in the latter, cancer and the degenerative diseases.

The research encompasses laboratory studies on the biochemical mode of action of environmental toxicants, exploratory studies aimed at improving the reliability and efficiency of predictive toxicological test improvement of diagnostic procedures for diseases possibly related to environmental factors, epidemiological investigations and field studies on the distribution of pollutants.

TITLE OF PROJECT

Rapid Screening for Lead Poisoning

USE THIS SPACE TO ABSTRACT YOUR PROPOSED RESEARCH. OUTLINE OBJECTIVES AND METHODS. UNDERSCORE THE KEY (NOT TO EXCEED 10) IN YOUR ABSTRACT.

While the causes and cure of lead poisoning are well known, early tection before effects become irreversible remains one of two major stumbling blocks to eradication of this environmental disease. Diagno tests so far devised have limitations and there is need for a practica reliable and definitive test. We propose to determine whether our qua tative computer/scanner system for rapid screening of radiographs can effectively detect lead poisoning in its early stages. We also intend evaluate the usefulness of our system in measuring the extraction of l from bones during treatment. Because of our capability for objective measurement we should be able to detect lead deposits in bones even wh they are not visible in radiographs. Our computerized system is wholl independent of subjective visual evidence and largely independent of f taking and processing variables, thus overcoming the drawbacks of trad tional radiographic screening methods.

We intend to analyze some 300 radiographs of known lead-poisoning by two of our standard methods for determining skeletal status: (1) m surement of radiographic bone size, weight and density combined with comparison of findings to normal values; (2) line-scanning of selected to establish a mineral distribution profile which may pinpoint dense d posits in growing ends of bones. If, as we expect, definitive pattern emerge, we will test our screening capability in a blind study which w include 150 lead-poisoning cases and 150 normal subjects.

We will follow progress of 50 or more patients receiving treatment by testing for significant changes in skeletal status in accordance with standard procedures.

LEAVE BLANK

National Institutes of Health,
Bethesda, Md., June 28, 1977.

Hon. Adlai E. Stevenson,
Chairman, Subcommittee on Science, Technology, and Space, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

Dear Senator Stevenson: This is in response to your and Senator Wendell H. Ford's letters of May 19, about Federal radiation research and regulatory programs, addressed to:

Dr. Donald S. Fredrickson, Director, National Institutes of Health
Dr. Guy R. Newell, Acting Director, National Cancer Institute (NCI)
Dr. Ruth L. Kirschstein, Director, National Institute of General Medical Sciences (NIGMS)
Dr. David P. Rall, Director, National Institute of Environmental Health Sciences (NIEHS)

Since the NCI, NIGMS, and NIEHS constitute three of the eleven component Institutes of the National Institutes of Health (NIH), we are submitting this single response for the entire agency.

The NIH is a research agency, and as such it both conducts research intramurally (by in-house staff) and supports research extramurally (through grants and contracts). We are *not* a regulatory agency but operate under the purview of various other agencies, such as the Nuclear Regulatory Commission (NRC). The NIH operates under a specific license of broad scope.

Safety aspects

1. Ionizing radiation.—The use of radioactive materials and other sources of ionizing radiation in the NIH intramural research program is under the careful regulation of the NIH Radiation Committee and the Radiation Safety Branch, Division of Research Services (DRS). [See Enclosure 1: NIH Radiation Safety Guide.]

It has been estimated that approximately 80 percent of the NIH intramural biomedical research effort is dependent, in varying degrees, upon the use of ionizing radiation for clinical or research purposes. The radiation safety program is responsible for over 3,000 scientists and support personnel who are working directly with radioactive materials or X-ray producing electronic products. Approximately 14,000 shipments of radioactive materials are received annually by NIH, with a total activity of 190 Curies, and a value of $2,500,000. This use has been increasing at a rate of approximately 15–20 percent over the past decade. In addition, there are over 150 X-ray producing devices under surveillance.

NIH radiation safety activities are planned to assure compliance with the applicable chapters of Part 10, Code of Federal Regulations, the conditions of the seven various licenses issued to NIH by the NRC, other applicable Federal regulations (FDA, DOT, EPA, OSHA, Postal Service, etc.), and all DHEW and NIH policies related to the safe and effective use of ionizing radiation. The Radiation Safety Branch, DRS, also provides a variety of essential health physics services, including: package receipt and delivery, radioactive waste disposal, license administration, instrument calibration and repair, bioassays, personnel exposure records, surveillance, training, effluent monitoring, and technical assistance, etc. The objective of the program is to provide assistance to the NIH intramural research scientist so as to maximize the benefits to be derived from the use of ionizing radiation in biomedical research, while concurrently reducing personnel exposures and releases of radioactive materials to unrestricted areas to the lowest levels reasonably achievable. The use of ionizing radiation as a tool for performing other studies should not be confused with primary radiation research. No primary ionizing radiation research or regulatory activities, in the context of this inquiry, are being conducted. Enclosure 2 provides data on your "Ionization Radiation" format for the NIH Radiation Safety Activities.

2. Non-ionizing radiation.—The Environmental Safety Branch (DRS) is responsible for monitoring and surveillance of intramural non-ionizing radiation activities. Approximately 0.2 man-years ($3,000–$4,000) has been devoted to this each year since 1968.

The NIH intramural research and support programs use a broad spectrum of non-ionizing radiation. The sources include lasers, microwave devices, ultraviolet lights, and ultrasonic devices. NIH employees are provided protection from the hazards of non-ionizing radiation through an ongoing monitoring and surveillance program that: Reviews source equipment purchase requisitions to insure that correct safety devices are a part of the equipment; monitors and interests and interprets new and existing standards and regulations for the use of non-ionizing sources; and surveys operating equipment to determine if safety equipment and procedures are functioning adequately.

Research

From the standpoint of research (as contrasted with service to assure safety), the NIH supports a very wide range of projects. Enclosure 3,[1] is a computer printout of extramural projects and intramural projects for fiscal year 1976 which will illustrate the broad scope encompassed by the terms "ionizing radiation" and "non-ionizing radiation" (and we have only queried the computer file for these as "primary" indexing terms).

While it is possible to secure similar extramural printouts for previous years, the abstracts of project descriptions are not available for fiscal year 1972 or earlier. It is not possible to obtain computerized retrieval of intramural projects for prior years.

In fiscal year 1976:

Ionizing radiation:	
1,483 Extramural projects	$122, 392, 501
49 Intramural projects	NA
Non-ionizing radiation:	
294 Extramural projects	17, 621, 200
29 Intramural projects	NA

Following are responses to two of your four specific questions:

Question 1. What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?"

Response. Changes in jurisdiction between 1968 and 1977, per se, have had little significant effect on NIH's overall effort in the radiation area. Specifically, the electronic product standards of the Bureau of Radiological Health, FDA, and the OSHA requirements have had very little impact. The NRC (formerly AEC) has had significant impact primarily as a result of continually increasing stringency of regulations in conjunction with the increased use of radioactive materials in biomedical research (166 percent increase at NIH since 1968). A very effective surveillance and compliance program is conducted by the NRC.

Question 2. Would you please describe the nature of the contracts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and federal agencies?"

Response. Although Maryland is an "agreement" State of the NRC, the nature of NIH's broad license is such that we deal directly with the NRC district office in King of Prussia, Pennsylvania. Contacts between NIH and various State groups in the radiation field are primarily referrals, consultations, license verification, and emergency preparedness.

There is little confusion concerning States' responsibilities, although they vary considerably from State to State; however, the responsibility of various Federal agencies such as NRC, EPA, DoT, ERDA, DoD, NBS, FDA, OSHA, U.S. Postal Service, etc., is a bit more obscure because of the large number involved, overlapping areas of interest, and the like.

Thank you for giving us this opportunity to provide comments on our radiation activities. We understand you will be hearing from the Department on questions 3 and 4. Please let us know if we can be of further assistance.

Sincerely yours,

DONALD S. FREDRICKSON, M.D.,
Director.

Enclosures.

---

THE NATIONAL INSTITUTES OF HEALTH RADIATION SAFETY GUIDE

U.S. DEPARTMENT OF HEALTH,
EDUCATION, AND WELFARE

Public Health Service

Office of Administrative Services
NIH Safety Guide Series

prepared by the
Radiation Safety Staff
Department of Nuclear Medicine
Clinical Center

Foreword

The 1972 edition of the NIH Radiation Safety Guide brings up to date the recommendations and requirements governing the use of radiation sources by the NIH Intramural Program.

NIH is using radionuclides in increasing quantities, under a specific license of broad scope issued by the U.S. Atomic Energy Commission. Possession of this license has greatly reduced the detailed problems of isotope procurement, but carries strict responsibilities governing use and ultimate disposal. NIH considers the AEC regulations as minimum requirements, and has broadened local controls to include radiation sources not under AEC surveillance.

Recommendations in the 1972 Guide have developed from years of experience in adapting general principles of radiation safety to the NIH environment. The procedures outlined in the Guide are designed to permit the maximum beneficial use of radiation sources with the minimum exposure to patients and personnel. Failure to follow the recommended procedures could result in a serious radiation overexposure, and a suspension or revocation of our license. All personnel using radiation sources are expected to become familiar with the NIH radiation safety requirements and to conduct their operations in accordance with them.

Robert Q. Marston, M.D.
Director,
National Institutes of Health

Introduction

The National Institutes of Health is authorized to procure and use radioactive materials on the Bethesda reservation under a "specific license of broad scope" issued by the Division of Materials Licensing of the Atomic Energy Commission. This license is contingent upon the existence of a Radiation Committee and a Radiation Safety organization which, among other requirements must:

1. Assure that any investigator using radioactive materials is qualified by training and experience, has the facilities to handle the materials safely, and proposes a use which is safe to all concerned.
2. Assure observance of all safety standards established by the Atomic Energy Commission, National Council on Radiation Protection and Measurements, and other regulatory or standards setting agencies.
3. Keep records of the receipt, storage, use, transfer, and ultimate disposal of all radioisotopes used at NIH.
4. Keep records of the monitoring of personnel and areas involved in the use of radionuclides and other sources of ionizing radiation.

NIH is subject to periodic inspection by the Division of Regulatory Operations of the Atomic Energy Commission to insure that all requirements of the license are being met. These inspections are very thorough, including monitoring checks of laboratory areas, inspection of procurement and disposition records, records of the qualifications of individual users, and records of administrations to patients. Violations of license requirements can result in a loss of the license.

All sources of ionizing radiation are not covered by the Atomic Energy Commission license. These sources are, however, controlled by regulations issued by the Director, NIH, upon recommendation of the Radiation Committee. Nonlicense sources include x-ray machines, high voltage accelerators, electron microscopes, and radioactive materials from sources other than reactor by-products.

This Guide describes rules and procedures required of NIH under the terms of AEC licensure, and for the use of non-licensed ionizing radiation sources as set forth by NIH regulations.

In total, the 1972 revision of the NIH Radiation Safety Guide represents several decades of intramural experience. Additionally, it reflects authoritative standards, guidelines, recommendations and research data concerning physical aspects and bioeffects of ionizing radiation obtained from the scientific literature.

The previous editions of this Guide included a reasonably comprehensive bibliography of the most important of these sources; the literature is now so extensive, however, that it is not feasible to include even a highly selective bibliography. Therefore, readers who desire documentation for any particular policy, procedure or quantitative data contained in these pages are invited to communicate directly with the NIH Radiation Safety office.

Although intended primarily for NIH personnel engaged in intramural laboratory and clinical investigation, past experience has shown the existence of a considerable external demand for copies of this Guide. To accommodate this demand more effectively, arrangements have been made with the U.S. Superintendent of Documents to place on sale single and bulk copies of the 1972 edition of the NIH Radiation Safety Guide.

National Institutes of Health Radiation Protection Guide

Ionizing radiation is among the most versatile and useful tools of modern medicine and biomedical research. Like many other instrumentalities of medicine and research, ionizing radiation is potentially hazardous unless used with strict adherence to safety rules and procedures.

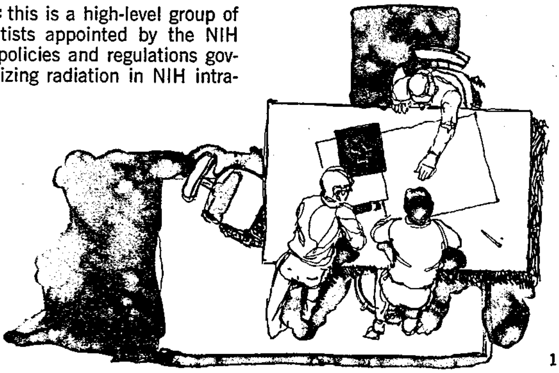
But unlike most other such hazards, the risk of unguarded exposure to ionizing radiation includes the possibility of damage to future generations. Thus the safety rules which govern all uses of ionizing radiation are as concerned with preventing genetic damage as with protecting the health of the exposed individual. When followed faithfully, these rules limit exposures of radiation workers to levels far below those which might cause any adverse somatic or genetic effects.

Because of the size and scope of its laboratory and clinical research programs, NIH is one of the world's largest users of ionizing radiation sources. These include radioisotopes, and isotope irradiators, x-ray machines, electron microscopes, and particle accelerators, all of which are essential to accomplishing the NIH mission.

The rules and procedures set forth in this Guide have one single, straightforward purpose—to protect NIH patients and employees against unnecessary and potentially harmful radiation exposure.

Four stages of group and individual responsibility are involved in the radiation safety program. All are equally important:

Radiation Committee: this is a high-level group of physicians and scientists appointed by the NIH Director to establish policies and regulations governing the use of ionizing radiation in NIH intramural programs.



Radiation Safety Office: an operating unit of especially trained health physicists and technicians which is responsible for NIH-wide compliance with these policies and regulations; it also provides a variety of technical services necessary to achieving such compliance.

Individual Users: physicians, scientists, other professionals, and technical and other workers engaged in patient care, clinical and laboratory research, and research support activities which involve actual use and handling of materials and devices producing ionizing radiation. These personnel usually work under the immediate supervision of Authorized Users.

Authorized Users: physicians and laboratory scientists whose training and experience are such that they have been authorized by the Radiation Committee to use ionizing radiation in their clinical care, clinical research, and laboratory research activities.

In the following pages detailed descriptions are given of the responsibilities of each of these four categories. Information is also provided on policies, rules and procedures for various particular aspects of ionizing radiation source procurement and usage. Careful observance of responsibilities, rules and procedures set forth in this Guide will insure more than adequate protection against unnecessary exposure to ionizing radiation.

Radiation Committee Responsibility

The Radiation Committee is composed of ten members appointed by the Director, NIH. The membership consists of one group of five physicians who are nominated by the Medical Board and, in conformity with AEC recommendations, is made up of one hematologist, one radiologist, one pathologist, one internist, and one physician with broad background in the use of radioisotopes. A second group of four scientists is nominated by the Scientific Directors. At least one of these scientists is to be a radiation physicist with training and experience in health protection. The Chairman of the Radiation Committee, the Radiation Safety Officer, and a representative of the Office of the Director are appointed by the Director, NIH. The Committee shall have jurisdiction over radiation sources and activities in areas under NIH control, including intramural program off-site use.

Functions

(a) Recommend policies regarding patient and plant radiation safety to the Director, NIH.

(b) Provide technical advice to the Radiation Safety Officer on matters regarding radiation safety.

(c) Receive, review, and act on all applications for the use of radiation sources in any areas used by NIH personnel. These sources include radioisotopes to be used in human subjects.

(d) Receive and review periodic reports from the Radiation Safety Officer on monitoring, contamination, and personnel exposure.

(e) Periodically review the overall use of radiation sources at NIH from the standpoint of operational hazards.

(f) Review all instances of alleged infraction of use and safety rules with the Radiation Safety Officer and the responsible Clinical and Scientific Directors before submitting reports or recommendations to the Director, NIH.

Radiation Safety Office Responsibility

The Radiation Safety office, under the direction of the NIH Radiation Safety Officer, is responsible for:

1. General surveillance of all health physics activities, including both personnel and environmental monitoring.

2. Furnishing consulting services to personnel at all levels of responsibility on all aspects of radiation protection.

3. Receiving, delivering, and shipping all radioactive materials coming to or leaving the NIH reservation.

4. Assaying and performing nuclidic purity checks on all radioactive materials to be used in humans for therapeutic purposes.

5. Monitoring all accelerators and other machines capable of producing penetrating radiations.

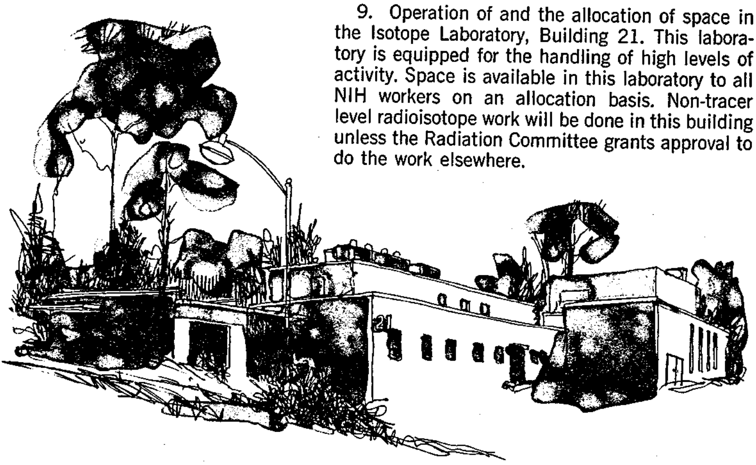
Calibrating the output of these machines as requested.

6. Distribution and processing of personnel monitoring equipment including the keeping of records of internal and external personnel exposure, and notifying individuals and their supervisors of exposures approaching the maximum permissible amounts and recommending appropriate remedial action.

7. Instructing personnel in proper procedures for the use of radioactive materials.

8. Supervision and coordination of the waste disposal program, including the keeping of waste storage and disposal records.

9. Operation of and the allocation of space in the Isotope Laboratory, Building 21. This laboratory is equipped for the handling of high levels of activity. Space is available in this laboratory to all NIH workers on an allocation basis. Non-tracer level radioisotope work will be done in this building unless the Radiation Committee grants approval to do the work elsewhere.



10. Storage of all radioactive materials not in current use.

11. Performing leak test on all sealed sources.

12. Maintaining a periodic inventory of all radioactive materials on the NIH reservation.

13. Supervising decontamination in cases of contaminating accidents.

14. Maintaining a continuous program of environmental radiation hazard evaluation and hazard elimination.

Individual User Responsibility

Each individual at NIH who has any contact with radioactive materials is responsible for:

1. Keeping his exposure to radiation as low as possible, and specifically below the maximum permissible exposure as listed in the following table:

	Rems per calendar quarter
Whole body; head and trunk; active blood-forming organs; lens of eyes; or gonads	1¼
Hands and forearms; feet and ankles	18¾
Skin of whole body	7½

Laboratory air and water concentrations shall be maintained below the levels listed in the Code of Federal Regulations, Title 10, Part 20 (10 CFR 20) "Standards for Protection Against Radiation." (See Appendix)

2. Wearing the prescribed monitoring equipment such as film badges and pocket dosimeters in radiation areas. Personnel who work only with pure alpha emitters or only with pure beta emitters having a maximum energy of less than 0.2 MeV will not be required to wear film badges.

3. Surveying his hands, shoes, and body for radioactivity, and removing all loose contamination before leaving the laboratory to smoke, eat, etc.

4. Utilizing all appropriate protective measures such as:
   - (a) Wearing protective clothing whenever contamination is possible, and not wearing such clothing outside of the laboratory area.
   - (b) Wearing gloves and respiratory protection when necessary.
   - (c) Using protective barriers and other shields whenever possible.
   - (d) Using mechanical devices whenever their aid will assist in reducing exposure.
   - (e) Using pipette filling devices. *Never pipette radioactive solutions by mouth.*
   - (f) Performing radioactive work within confines of an approved hood or glove box unless serious consideration has indicated the safety of working in the open.

5. Avoiding smoking or eating in isotope laboratories. It is recommended that eating be done in the cafeterias whenever possible. Smoking or eating may be permitted in an office area of a laboratory that has been demonstrated to be free of contamination. Refrigerators shall not be used jointly for foods and radioactive materials.

6. Maintaining good personal hygiene.
   - (a) Keep fingernails short and clean.
   - (b) Do not work with radioactive materials if there is a break in skin below the wrist.
   - (c) Wash hands and arms thoroughly before handling any object which goes to the mouth, nose, or eyes.

7. Checking the immediate areas, e.g., hoods, benches, etc., in which radioactive materials are being used, at least once daily for contamination. A log record should be maintained of these surveys including results which are entirely negative. Any contamination observed should be clearly marked and the Radiation Safety office notified.

8. Keeping the laboratory neat and clean. The work area should be free from equipment and materials not required for the immediate procedure. Keep or transport materials in such a manner as to prevent breakage or spillage (double container), and to insure adequate shielding. Wherever practical, keep work surfaces covered with absorbent material, preferably in a stainless steel tray or pan, to limit and collect spillage in case of accident.

9. Labeling and isolating radioactive waste and equipment, such as glassware, used in laboratories for radioactive materials. Once used for radioactive substances, equipment should not be used for other work, and *shall not be sent from the area to central cleaning facilities, repair shops, or to surplus, until demonstrated to be free of contamination.*

10. Requesting Radiation Safety office supervision of any emergency repair of contaminated equipment in the laboratory by shop personnel or by commercial service contractors. At no time shall servicing personnel be permitted to work on equipment in radiation areas without the presence of a member of the laboratory staff to provide specific information.

11. Reporting accidental inhalation, ingestion, or injury involving radioactive materials to his supervisor and the Radiation Safety office, and carrying out their recommended corrective measures. The individual shall cooperate in any and all attempts to evaluate his exposure.

12. Carrying out decontamination procedures when necessary, and for taking the necessary steps to prevent the spread of contamination to other areas.

13. Complying with requests from the Radiation Safety office for body burden measurements in the whole body counter and the submission of urine samples for radioassay. Requests for these tests will be made in the case of workers using significant quantities of both γ and β emitters.

Authorized User Responsibility

Authorized users are responsible for insuring that the preceding individual responsibilities are discharged by those under their control, and are further responsible for:

1. Adequate planning. Before an experiment is performed, the supervisor should determine the types and amount of radiation or radioactive material to be used. This will generally give a good indication of the protection required. The procedure must be well outlined. In many cases, before the procedure is actually performed with radiation, it should be rehearsed so as to preclude slip-ups or unexpected circumstances. In any situation where there is appreciable radiation hazard, the Radiation Safety office shall be consulted before proceeding.

2. Instructing those employees for whom they are responsible in the use of safe techniques and in the application of approved radiation safety practices.

3. Furnishing the Radiation Safety office with information concerning individuals and activities in their areas—particularly, pertinent changes in their personnel rosters.

4. Contacting the Radiation Safety office whenever major changes in operational procedures, new techniques, alterations in physical plant (e.g., the removal of radiochemical fume hood), or when new operations which might lead to personnel exposure are anticipated.

SAFTY & WASTE
DISPOSAL

5. Complying with the regulations governing the use of radioactive materials, as established by the AEC and the NIH Radiation Committee, for:
    - (a) Correct procedure for the procurement of radioactive materials by purchase or transfer. (See procedure for Procurement of Radiation Sources.)
    - (b) Posting areas where radioisotopes are kept or used, or where radiation fields may exist.
    - (c) Seeing that each sign carries the name of the personnel currently responsible for the associated area.
    - (d) Recording the receipt, transfer, and disposal of radioactive materials in his area. This includes sealed sources such as ion sources in gas chromatographs and static eliminators. The authorized user must be prepared to submit semiannually the required inventory data upon request.
    - (e) Assuring that all radioactive waste materials are consigned to the Radiation Safety office for disposal.
    - (f) Taking steps to prevent the transfer of radioactive materials to unauthorized individuals. This includes the proper disposition of radioactive materials possessed by terminating workers.

6. Keeping stocks of stored radioactive materials to a minimum within laboratory areas. Authorized users should employ the storage facilities of the Isotope Laboratory, Building 21, for shipments not needed in current research.

7. Complying with proper procedure for termination of employment or termination of any experiment using radioactive materials. The authorized user is reminded that, under the terms and conditions of the AEC-NIH license, he must return to the Radiation Safety office all radioactive materials, including waste, assigned to him under the license. Particular care should also be exercised to see that specialized equipment such as personnel monitoring devices (e.g., film badges), survey instruments, and shielding materials are returned to the Radiation Safety office. A final termination survey should also be requested by telephone.

Policies and Procedures for Radioisotope Areas

In addition to the Code of Federal Regulations, Title 10, Part 20, "Standards for Protection Against Radiation," as appended to the Guide, the following policies and procedures will apply to the NIH license:

1. Proper Marking of Laboratories, Areas, and Equipment

   (a) A "CAUTION RADIOACTIVE MATERIALS" sign must be conspicuously posted on the doors to laboratory areas where radioactive materials are being used or stored. The name and home phone number of the individual responsible for the posted area shall be shown in the designated place on the sign in order to facilitate contact in case of emergency. The supervisor shall be responsible for seeing that the posted information is current. The signs must not be removed from any room except by Radiation Safety personnel following an inspection survey.

   (b) Storage areas shall be conspicuously marked with a "CAUTION RADIOACTIVE MATERIALS" sign. In addition, containers in which materials are transported or stored shall bear a durable, clearly visible label bearing the radiation caution symbol and the words "CAUTION RADIOACTIVE MATERIALS." This label shall also state the quantities and kinds of radioactive materials in the containers and the date of measurement of the quantity.

   (c) Radiation areas in the laboratory, i.e., areas where radiation levels might expose individuals to 5 millirem in any one hour; or in any five consecutive days, a dose in excess of 100 mrem, shall be posted with the sign "CAUTION RADIATION AREA."

   (d) All equipment contaminated with radioactive material shall be marked with signs, decals, or other conspicuous means. Labeling shall not be required for laboratory containers such as beakers, flasks, and test tubes, used transiently in laboratory procedures during the presence of the user.

(e) All signs referred to in this part are available from the Radiation Safety office, Building 21.

2. Shielding of Sources

(a) Radioactive sources or stock solutions in the laboratory shall be shielded in such a manner that the radiation levels in any occupied area will not expose individuals in the area to more than 100 mrem in any five consecutive days.

(b) Various shielding materials are available on loan from the Radiation Safety office.

3. Aerosols, Dusts, and Gaseous Products

(a) Procedures involving aerosols, dusts or gaseous products, or procedures which might produce airborne contamination shall be conducted in a hood, dry box, or other suitable closed system.

(b) All releases from such systems shall not exceed the maximum permissible concentration in air for the nuclide in question. See Appendix B, Table II of 10 CFR 20 for appropriate values. However, where practical, traps should be incorporated in the experimental set-up to insure that environmental releases are as low as possible.

(c) Radioactive gases or materials with radioactive gaseous daughters must be stored in gas-tight containers and must be kept in areas having approved ventilation.

(d) Hoods to be used for radioisotope work should be tested by the Environmental Services Branch, DRS, to insure that they meet the minimum requirements for air velocity at the face of the hood.

4. Sealed Radioactive Sources

(a) All sealed radioactive sources must be shipped to: Radiation Safety Officer, National Institutes of Health, Building 21, Isotope Laboratory, Bethesda, Maryland 20014. Each source must be registered with this office.

(b) For those sources which may change location frequently, the Radiation Safety office in cooperation with individual users shall establish strict accountability procedures.

(c) Sealed sources shall be leak tested by Radiation Safety personnel prior to initial use and at least every six months thereafter.

5. Radioactive Materials in Gas Chromatography Equipment

All gas chromatography units in which radioactive materials are to be used are regulated as follows:

(a) As is true with other radioactive shipments, radioactive foils to be used in gas chromatography cells must be shipped to: Radiation Safety Officer, National Institutes of Health, Building 21, Isotope Laboratory, Bethesda, Maryland 20014. Each foil must be registered by number with this office.

(b) In addition, each cell containing a radioactive foil must have a label showing:

The radiation caution symbol with the words "CAUTION RADIOACTIVE MATERIAL"; and

The identity and activity of the radioactive material.

The radioactive foil shall not be removed from its identifying cell except for cleaning and shall not be transferred to other cells.

(c) The following notice shall appear in a conspicuous location on the outside of each gas chromatography unit: "This equipment contains a radioactive source registered with the NIH Radiation Safety office as required by license from the Atomic Energy Commission. Notify the Radiation Safety office before removing the source from this room or area or upon any change in custodial responsibility." These notification tags are available from the Radiation Safety office, Building 21.

(d) Individuals using radioactive components in gas chromatography equipment must vent the cell-exhaust through plastic tubing into a hood, room exhaust, or Radiation Safety approved trap, to avoid contamination of work areas from the release of radioactive tagged samples introduced into the system or from the accidental overheating of radioactive foils in the cells.

(e) The Radiation Safety office will perform periodic leak tests, store radioactive foils when not in use, and maintain the necessary records on such tests and storage.

6. Work Surfaces

All work areas (bench tops, hood floors, etc.) as well as storage areas and areas adjacent to permanent set-ups and sinks should be covered at all times with stainless steel or plastic trays, uncracked glass plates, or other impervious materials. For some purposes a plastic-backed absorbent paper (e.g., "Kimpak", available from the Central Storeroom) will be satisfactory. However, if such paper is used, it should be discarded frequently to prevent active materials from dusting off the surface.

7. Periodic Surveys of Radiation Areas

The immediate areas (e.g., hoods, bench tops) in which radioactive materials are being used should be checked for contamination at least once daily by the radiation workers in that laboratory. In addition, these areas should be inspected each and every time there is reason to suspect a contamination incident. *Records shall be kept on both positive and negative survey results in the authorized user's laboratory logs.*

8. Laboratory Monitors

Each laboratory or area (other than those where ^{3}H is used exclusively or where only exempt quantities of other radionuclides are handled) shall be equipped with a portable or semiportable monitoring device to be used for personnel and area monitoring. Laboratory monitors of this type are available on loan from the Radiation Safety office.

9. Removal of Equipment from the Laboratory

Once used for radioactive substances, equipment shall not be used for other work, or sent from the area to central cleaning facilities, repair shops, surplus, or returned to the source of supply, until demonstrated to be free of contamination. Equipment to be removed from the Isotope Laboratory, Building 21, must be cleared through the Radiation Safety office.

10. Repair and Maintenance of Equipment in the Laboratory

Equipment to be repaired by shop and maintenance personnel, or by commercial service contractors, shall be demonstrated to be free of contamination prior to servicing. If it becomes necessary to make emergency repairs on contaminated equipment, the work will be supervised by a member of the Radiation Safety office staff, who will assure that the necessary safeguards are taken. It is the responsibility of the laboratory personnel to request this supervision from the Radiation Safety office.

11. House Vacuum Lines

House vacuum lines are vulnerable to contamination. If house vacuum lines are to be used, the withdrawn gas must be demonstrated to the Radiation Safety office to be free of radioactivity. It is advisable to use a separate vacuum system whenever possible, such as a separate vacuum pump exhausting into a hood.

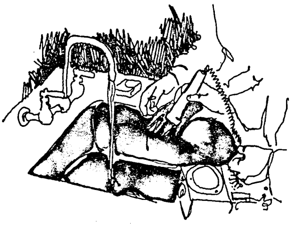
12. Radioactive Contamination of Areas

In general, no radioactive contamination can be tolerated. Exceptions to this will include certain hood trays, dry boxes, stainless steel trays, Kimpak covered surfaces, or other equipment which is used frequently for active work and which will be clearly marked with the standard radiation caution signs or stickers. Any contamination that is not confined to protected surfaces should be reported immediately to the Radiation Safety office. The Radiation Safety staff will supervise the decontamination of such areas or equipment.

13. Decontamination of Areas Contaminated with Radioactivity

Preparations for decontamination should be begun promptly. Determine the extent and 13 hazard of contamination. The Radiation Safety office staff will assist in this evaluation. The individual responsible for the contamination will be expected to do most of the cleanup under the supervision of the Radiation Safety staff. After decontamination, the area or equipment shall be considered contaminated until proved otherwise by the Radiation Safety office.

14. Decontamination of Personnel Contaminated with Radioactivity



(a) Notify supervisor immediately after contaminating accident.

(b) Wash body area involved thoroughly for 2 or 3 minutes, repeatedly "soaping" and rinsing. Consideration should be given to the chemistry of the contaminant and an attempt made to find a suitable agent for dissolving it. Any cleansing agent may be used, but synthetic detergents are preferred to soaps. Avoid prolonged use of any one decontamination procedure. Irritation of the skin may impede the success of more suitable procedures. Avoid the use of organic solvents. They may make the skin more permeable to radioactive contaminants.

(c) If this procedure is not immediately and completely effective, notify the Radiation Safety office and proceed at once to the Medical Officer in charge of the Building 10 Health Unit, Employee Health Service. Special decontaminating agents such as "Versene", "Radiacwash", etc. may be used under the direction of the Medical Officer.

15. Prophylactic Thyroid Blocking Agents in Laboratories Using Radioiodine

Individuals utilizing greater than 10mCi radioiodine should consult with and follow the recommendations of the Employee Health Service prior to the use of prophylactic thyroid blocking agents. Such individuals are reminded that the use of these blocking agents in no way reduces the need to take all other precautions in the safe handling of radioiodine.

Radioactive Waste

No radioactive wastes shall be disposed of by conventional methods. This means particularly that solid wastes may not be placed in the standard waste containers to be collected by housekeeping personnel, and that liquid wastes may not be discharged into the sewer. Animals must not be incinerated in the general purpose incinerator.

No radioactive waste shall be released from a laboratory area for pickup and disposal prior to autoclaving or otherwise suitable deactivation of infectious agent(s). Radioactive waste disposal procedures in the waste handling area of the Isotope Laboratory, Building 21, involve crushing and compacting of dry wastes by compaction devices and pooling of liquids in approved shipping containers for disposal by a licensed contractor. These procedures are not compatible with the proper handling of infectious agents. Similar considerations shall also be given to other highly toxic or hazardous substances. (See Section 3)

1. Waste Containers

   To insure that solid and liquid wastes are kept separate, each laboratory having radioactive waste must be equipped with at least one container for solid dry waste and one for liquid waste. Due to the methods of ultimate disposal of waste by the Radiation Safety office, short half-life (less than 30-days) waste must be kept separate from long half-life waste. Additional waste containers shall be requested for this purpose and marked as to the isotopes being used.

   (a) Solid dry waste containers. These may be obtained from the Radiation Safety office. They must be kept fitted with a disposable waterproof polyethylene liner.

   (b) Liquid waste containers. Plastic carboys, glass jars, or bottles are suitable for storage of liquid wastes. If the liquid waste container is glass or ceramic, then it must be kept in such a manner that if accidentally broken, the contents will be retained in a small area, e.g., having it set in a large pan. These liquid containers must possess securely fitting covers or corks, and must be kept closed. In addition, they shall be conspicuously marked with appropriate radiation signs.

(c) Animal carcasses. Small radioactive animals should be placed in the standard polyethylene bags. Larger animals (dogs, etc.) should be placed in large polyethylene bags which will in turn be placed in a GI can. Each unit must be conspicuously marked with a "CAUTION RADIOACTIVE MATERIAL" sign and in addition, the isotope(s) and amount remaining in the carcass shall be posted on the bag or label. If pickup cannot be arranged within 4 hours of sacrifice of animals, such animal carcasses must be refrigerated or preferably frozen.

(d) Liquid scintillation vials. All liquid scintillation vials must be disposed of as radioactive waste. Prior to removal, all liquid scintillation vials must be tightly capped and returned to the original shipping trays.

2. Waste Pickup

Request for removal of liquid and dry waste may be made by telephone to the Radiation Safety office. At the time of the telephone request and at time of pickup, the investigator must be able to estimate, with a fair degree of accuracy, the amount of radioactive waste in each container.

3. Unusual Waste Disposal Problems

Plans for proper disposal of infectious agents or highly toxic or hazardous substances shall be made early in the design stage of the experiment.

Proposed procedures involving unusual waste disposal problems will be considered individually by the Radiation Committee or the Radiation Safety Officer and staff.

Physician's Responsibility and Procedures

In carrying out the responsibilities and duties assigned it by the AEC under the Broad License and by the Director, NIH, the Radiation Committee requires compliance with the following policies and procedures:

1. Experience and Training of Applicants

   The Committee is bound by the requirements of AEC for training and experience of physicians in the use of radioactive materials. These requirements are listed in "Atomic Energy Commission Licensing Guide—Medical Programs," November 1965. Copies of this report are available for reference from both the Radiation Committee office and the Radiation Safety office.

2. Procedures for Making Application to the Committee

   A separate application is required for each project which contemplates the use of radioactive materials in humans. This application must include:

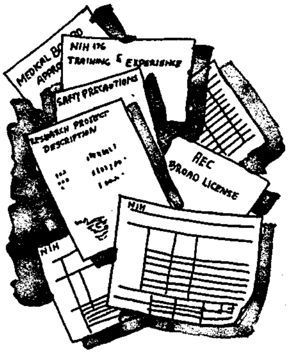
   (a) Form NIH–176: A self-explanatory form available from the Chairman, Radiation Committee.

   (b) Narrative description of project which shall include:

   (1) Title of the project.

   (2) A statement of the purpose and justification for the use of radionuclides.

   (3) Description of the project; including methods, characteristics of radioactive materials (half-life, nature and energy of emissions, modes of decay), details of doses (single and total) and



the anticipated results. Reference to previous work published by the Applicant or others concerning animal experimentation or human use (including doses) should be carefully documented. The Committee requires a clear, concise calculation of the anticipated whole body and critical organ absorbed dose in rads, stating the period of such exposure and radiation hazards, if any. Include uptake and excretion data. The formula used for such calculation should be clear, all terms defined, and the source and estimated reliability of the formula indicated. Assumptions used for estimates should be stated. Assay methods and estimated efficiencies should be given.

(4) Methods of waste disposal, particularly with respect to urine, stools, exhaled air, and calculation of the daily amounts of radioactivity to be disposed of into the sewer or air, if any.

(5) Safety precautions which will be initiated to protect the patient, other patients in the vicinity of the radioactive patient, and the patient-care staff and adjunct personnel.

(6) If the use of the radioactive material is planned for normal human subjects, the application must specify minimum ages of these subjects, the fact that they are volunteers, cognizant of the possible radiation hazards, and the status of such normal subjects with respect to other contacts with radiation, and cumulative exposure. In addition, the Radiation Committee requires a short statement from the investigator regarding the information he would supply to the volunteer pursuant to obtaining his consent.

(c) With the first application from each investigator, a complete description of his training and experience, stating periods, location and supervision in the use of radionuclides (Form NIH–465–1,–2).

Upon completion, this application should be forwarded through the Branch Chief, and the Clinical Director of the applicant's Institute to the Chairman of the Radiation Committee. Action of the Committee will be returned through channels to the applicant and copies will be forwarded to the Radiation Safety Officer and to the Chief, Radiopharmaceutical Section. The signed approved original will constitute the investigator's authorization under the Broad AEC License to procure and use the materials. Physicians may obtain information on current approved investigators and specific medical uses at NIH from the Radiation Committee office.

Should questions arise in the Committee regarding details of an application, the investigator will be invited to meet with the Committee and discuss the details of his proposal. Should the Committee finally disapprove the application on the basis of conflict with restrictions of the AEC or Director, NIH, or Committee policies, the application nevertheless will be forwarded to AEC for its review and action upon further recommendation of the investigator and his Clinical Director.

Each authorization will be marked with an expiration date which will usually be the last day of the month, one year after the month of the approval. Authorized investigators should anticipate the expiration of their approvals by at least one month and apply for renewal of the authorization. For this purpose, it is necessary to submit only the Form NIH-176 (without narrative description) and a "Summary of Use of Radioactive Materials," Form NIH-465-3. The investigator should clearly state that this is an application for renewal of the previous authorization without modification, and should include the number of the original authorization and date.

If an investigator has no positive plans for the use of a given authorization during the coming year, he should consider its retirement in order to save on bookkeeping in the Radiation Committee, Radiation Safety and Radiopharmacy offices. Such a retired authorization can usually be reactivated by the Chairman, Radiation Committee, in one day should need for it develop.

An authorization which is being considered for renewal and which reflects frequent patient use may be retained and established as a service to be provided to the clinician and patient by the Department of Nuclear Medicine. Decision to provide this service will reside with the Chief, Department of Nuclear Medicine. This service consideration would also be applied in the situation where several similar authorizations by separate applicants reflect an overall need for patient service from various areas of the Clinical Center.

After receiving the approved Form NIH–176, the investigator should comply with the procedures "Procurement of Radiation Sources" listed elsewhere in this Guide.

3. Responsibility

   The authorized investigator has primary responsibility for the use of the radioactive material; for the protection of the patient, and for the safe handling of any material removed for study. The Radiation Safety staff is responsible for the protection of the patient-care staff, for instructions needed to insure radiation-safe conditions, and for the handling of contaminated materials, equipment, and waste. *Any delegation of work does not shift responsibility.*

   Special instructions regarding patient treatment shall be on Clinical Record SF–508. Radiological safety precautions will be recorded on Form NIH–876.

4. Justification

   The widely accepted policy for medical uses of radioisotopes is that radioactive substances should never be used in humans except when the investigation or treatment justifies the risk involved. It is NIH policy to encourage use of the most sensitive instrumentation and assay procedures available, and to promote progressively better techniques aimed at reducing radiation doses. All research and diagnostic procedures should be designed with these policies in mind.

   The therapeutic uses of radiation in other than malignant disease should be well justified. Applications for therapeutic uses of radiation will be reviewed by the Radiation Committee in accordance with instructions from the Director, NIH, and the Medical Board.

5. Dosage Considerations

   As a general guide to the maximum permissible dose for normal volunteers and for patients, the Radiation Committee follows the recommendations of the National Council on Radiation Protection and Measurements Report No. 39, "Basic Radiation Protection Criteria." Insofar as is practical, the Committee considers that exposure of normal subjects and patients should be limited to these values when diagnostic and experimental purposes permit. When it is necessary to exceed this dosage for the purposes of research or diagnosis because instrumentation of the required sensitivity is not available, the applicant will be required to provide justification for exposures higher than 3.0 rads to any tissue within a 13-week period, and if such exposure occurs in a single dose, assurance that the human subject or patient will not receive further radiation for a subsequent period of one year. For all normal subjects and patients under the age of 18 years and all pregnant women, this limit is reduced to 0.30 rads.

Larger doses will be considered by the Committee for use in patients with limited life expectancy (two years or less) when the application adequately justifies the procedure and the importance of the contribution which is anticipated by the use of such doses.

When considering the utilization of radioactive materials for human research and diagnosis, the investigator is urged to carefully consider the following factors:

- (a) Body retention of the radioactive materials.
- (b) Accumulation in critical tissues.
- (c) Size of critical organ.
- (d) Radiosensitivity of the tissue.
- (e) Biological half-life.
- (f) Effective half-life.
- (g) Type and energy of the radiations.
- (h) Accumulation of effects of combined or sequentially administered radioactive materials.
- (i) Concomitant use of x-radiation.

6. Calibration and Nuclidic Purity Tests

   Prior to administration, all radionuclides are to be calibrated and tested for nuclidic purity by the Radiopharmaceutical Section. Indicated pyrogen and sterility testing is to be arranged by the Radiopharmaceutical Section.

7. Notification of Nursing Staff

   In order that the nursing staff may prepare for therapeutic isotope administration, the head nurse of the nursing unit which will care for the patient should be notified as far in advance as possible, preferably 24 hours or more. Those connected with the administration of radioactive isotopes should become familiar with nursing procedures to insure uniformity of precautions.

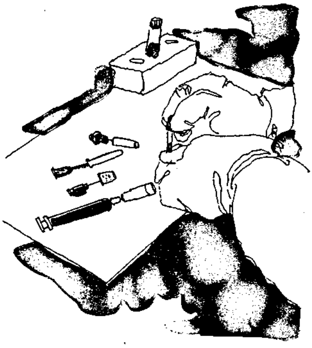
8. Area Designation

   It is not necessary to isolate patients with routine diagnostic doses nor to post their rooms. Patients with therapeutic doses should be confined to their individual rooms, as distant from the nursing station as feasible, and the room posted with a "Radiotherapy Precautions" sign (available from the Radiation Safety staff). The Radiation Safety staff will conduct daily surveys of the patient area following therapeutic doses, removing contaminated materials such as urine, soiled bedding, etc., when necessary, and instituting controls so that the patient-care staff, adjunct personnel, and visitors are not exposed to radiation levels in excess of applicable guides. The physician in charge is responsible for requesting assistance from the Radiation Safety staff in the event of contaminating accidents, and prior to removal of the patient from therapy precautions.

9. Record of Patient Doses
The authorization number and any dose of a radioisotope administered to a patient together with the other required data shall be recorded immediately on the patient's chart using Form PHS–2201, "Radioactive Isotope Exposure Record."

10. Radioactive Waste and Disposal
Radioactive contamination of room air and sewerage should not exceed the limits approved by the AEC as stated in 10 CFR 20 (found elsewhere in this Guide). When wastes exceed these limits, they shall be disposed of with the assistance of the Radiation Safety staff.

11. Radioactive Contaminated Equipment
The authorized physician is responsible for arranging for the safe disposal of all radioactive solutions and contaminated equipment such as syringes, etc. This may be accomplished by removal to the individual's laboratory for proper decontamination or storage for decay, or by contacting the Radiation Safety staff for disposal. Under no circumstances should such solutions or equipment be left on the nursing unit, or the responsibility for disposal of these materials be delegated to the nursing staff. The Radiation Safety Officer strongly recommends the use of disposable syringes and needles for the administration of radionuclides. Disposable syringes containing only the usual residual fluid may be disposed of in the regular dry radioactive waste containers available on the nursing units. Disposable needles may also be put into the regular dry radioactive waste containers ONLY after they have been capped or after the needle point



has been inserted in a small cork. This is necessary in order to preserve the integrity of the plastic bag lining the container and to protect personnel handling these liners.

12. Laboratory Specimens

There exists a danger that highly radioactive tissue specimens, blood, ascitic fluid, excreta, or cadavers may be delivered to the laboratory or pathology services, without being adequately labeled. To minimize this possibility, all specimens from such patients which are to be sent to a laboratory must be labeled "Radioactive." Preferably, the laboratory should be called in advance to give them additional information, such as the amount of activity and special handling techniques required, if any. This includes tissue specimens, ascitic fluid, blood, urine, feces, emesis, etc.

Exemptions:

(a) When the time elapsed between the administration of the radionuclide and the time of obtaining the specimen is such as to render the specimen (in the opinion of the physician in charge of the patient or in the opinion of the Radiation Safety Officer) no longer a hazard from either a health or a contamination standpoint.

(b) When the radionuclide is administered in such a way that it remains localized and does not enter significantly into the general circulation (such as colloidal gold injected into the prostate), and the specimen is excreta or a tissue removed at a site sufficiently distant from the injection site so that it is unlikely to contain any of the radioactive material.

13. Cadavers

If a patient who has received a therapeutic dose of any radioisotope dies in the hospital within a three (3) week period after that dose, the authorized physician is requested to do the following:

(a) Tie a radioactive hazard sign to the body writing on it the specific isotope, the amount given, and the date of administration.

(b) Place the Form PHS–2201 as the top sheet in the chart and write across the face of this sheet "Radioactive Body."

(c) Notify the Radiation Safety Officer. During off-duty hours the Guard Office in Building 31 should be requested to notify one of the persons on the call list maintained for such emergencies. The Radiation Safety Officer must be notified as he is responsible for giving the pathologist suitable safety instructions and for giving the required information to the funeral director.

Procedures for Nursing and Patient Care Staff

1. Diagnostic Procedures

Since there is minimal external hazard to others from routine diagnostic doses of radionuclides, there are no restrictions on the patient's activities or his contacts with other people. Nursing personnel are not required to wear personnel monitoring devices.

The following procedures apply when a patient receives radioactive material for diagnostic purposes:

(a) The Chief Nurse of the unit should request a Geiger counter and dry radioactive waste can from the Radiation Safety staff to be kept in the utility room.

(b) Patient-care personnel should use disposable gloves to handle items suspected of contamination. Particular care should be exercised in the handling of vomitus and excreta during the first 24 hours following administration of the radionuclide. Use the Geiger counter to check for contamination. Contaminated linen should be placed in a yellow laundry bag which is kept in the patient's room. Other contaminated items should be placed in the radioactive waste container. Call the Radiation Safety office for removal of such contaminated linen and waste.

(c) Laboratory samples taken during the first 24 hours post administration should be labeled "Radioactive."

(d) Special diagnostic procedures will be evaluated on an individual basis and appropriate written instructions may be issued.

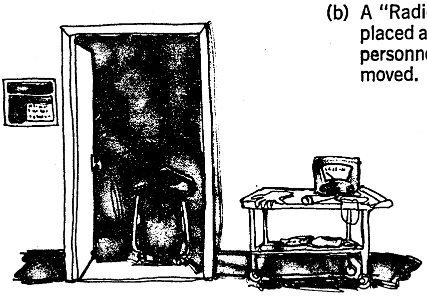
(e) Should questions arise concerning the use of radionuclides on a unit, call the Radiation Safety staff for assistance.

2. Therapy Procedures

The following procedures apply when patients receive radionuclides other than sealed sources or colloidal suspensions, in millicurie amounts for therapeutic purposes:

(a) Special Radiation Safety Procedures (Form NIH–876) will be issued to the Chief Nurse of the unit at the time the radioisotope is given or at the time the patient is returned from the operating room. This form will indicate precautions to be taken on a daily basis and will be reviewed each day by Radiation Safety personnel.

(b) A "Radiotherapy Precautions" sign shall be placed at the patient's door. Radiation Safety personnel will indicate when it may be removed.



(c) The patient should be put in a room by himself. For patients receiving gamma-emitting nuclides, this room should be as distant from the nursing station as feasible. *Exception:* Patients receiving radiation source implants (radium or iridium needles) or colloidal suspensions may be placed in a room with another patient providing this second patient is receiving external beam therapy.

(d) Handling of Patient

1. When indicated on the Form NIH–876, the patient-care staff should wear dis-

posable gloves while handling the patient. Used gloves should be placed in the radioactive waste can for disposal.

2. Wash hands thoroughly with soap and running water after gloves are removed.
3. After handling the patient, patient-care personnel should monitor themselves thoroughly using the Geiger counter provided for this purpose.

(e) Food Service

If feasible, paper plates and disposable utensils should be used by the patient during therapy precautions. If found contaminated after use, they should be placed in the waste container provided for this purpose.

(f) Patient's Linen

All linen, i.e., bedclothes, pajamas, towels, etc., used during the period of therapy precautions must be placed in a yellow laundry bag to be kept in the patient's room, and must not be sent to the laundry until monitored by Radiation Safety personnel.

(g) Removal of Objects and Materials From Patient's Room

All objects or materials to be removed from the therapy precautions area shall be checked for contamination. It may be necessary to remove these articles temporarily to the utility room for monitoring, due to the radiation levels in the vicinity of the patient.

(h) Disposal of Radioactive Excreta

1. Feces should be passed in the toilet whenever possible. If a bedpan is used, it must be handled with disposable gloves. The same bedpan should be used until treatment is completed and its use restricted to that particular patient.
2. Urine shall be saved in stoppered bottles and if the isotope is a gamma-emitter, the bottles shall be kept in a shielded storage container provided by the Radiation Safety staff. Urine container, urinals, specimen bottles, etc., should be handled only by the patient if at all possible.

(i) Housekeeping Personnel
Housekeeping personnel shall not enter the room unless indicated on the Form NIH-876.

(j) Accidents
In case of an accident which might produce a radiation hazard (e.g., the spillage of contaminated urine on the floor),

CALL AT ONCE:
During Regular Working Hours
The Physician in Charge,
Radiation Safety Officer,
and
Chief of Nursing Service.
Outside of Regular Working Hours:
Nursing Supervisor in Charge,
Physician in Charge,
and
Guard Office in Building 31 for names of
Radiation Safety office personnel on call.

3. Colloidal Suspensions and Sealed Sources

The following apply when patients receive therapy utilizing colloidal suspensions or sealed sources, such as needles, tubes and plaques containing iridium-192, cobalt-60, radium, radon, etc.:

(a) All dressings, bedclothes, sanitary napkins, bedpans, etc., or any material removed from the vicinity of the treatment site shall be carefully monitored to assure that the source has not been removed or displaced.

(b) The above-mentioned items (a), (b), (c), and (i) of Part 2 shall also apply.

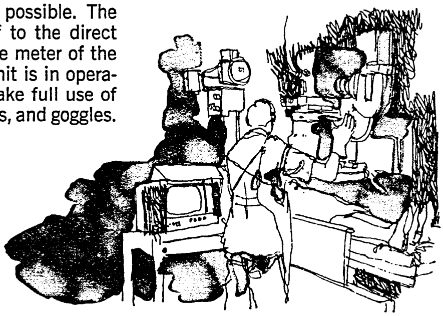
(c) Items (d), (e), (f), (g), and (h) do not apply to these cases since there is little if any chance of contamination.

(d) The nursing staff should be alert to any sealed sources which may have moved from their original positions. Should an implanted source become separated from the patient, proceed as in 2-(j) above.

Radiation Producing Equipment Operator's Responsibility

The operator of any radiation producing equipment is responsible for:

1. Notifying the Radiation Safety office when there is any change in the setup, i.e., new equipment installed, changes in shielding, change in output of radiation, or change in usage of the unit.
2. Requesting and wearing appropriate monitoring devices. Always wear the assigned monitoring device (e.g., film badge) when working with the unit. Whenever protective lead aprons are worn, the body monitor should be worn on the outside of the apron at the neckline. In addition, wrist monitors are to be worn if the unprotected hands and forearms must come in close proximity to the beam.
3. Keeping exposure as low as possible. The operator must never expose himself to the direct beam, and must not stand within one meter of the tube or irradiated target while the unit is in operations unless adequately shielded. Make full use of protective barriers, lead aprons, gloves, and goggles.



4. Clearing the area of all nonessential personnel. The operator should insist that all nonessential personnel leave the exposure area before operating the unit, and that all essential personnel be adequately shielded.
5. Observing any restrictions on the use of the unit recommended by the Radiation Safety staff.
6. Adequate dark adaptation. The eyes of the fluoroscopist should be well dark-adapted before he uses a fluoroscope without image intensifying equipment. It is inexcusable to increase the output of the unit to compensate for poor dark adaptation.
7. Using minimum exposure factors. Fluoroscopic work shall be performed in the minimum time possible using the lowest dose rate and smallest aperture consistent with clinical requirements.

8. Visually monitoring tube current and potential of fluoroscopic equipment with image intensifiers at frequent intervals, because under automatic brightness control these variables can rise to high values.

9. Recording data of fluoroscopic and cineradiographic studies on patients on Form NIH-378, "Radiation Exposure Record," and maintaining this form in the patient's record.

10. Notifying the supervisor and the Radiation Safety Officer immediately of any accidental exposures to radiation.

11. Keeping the unit disconnected or locked when not in actual use.

Policies for Radiation Producing Machines and Areas

1. All operating personnel and personnel in the immediate area will be required to wear a film badge or other personnel monitoring device.

2. Areas in which radiation producing machines are located or are being used shall be posted with the characteristic "CAUTION RADIATION" sign. In addition, the controls shall bear a decal with the statement: "CAUTION RADIATION—This equipment produces radiation when energized." Labels and decals are available from the Radiation Safety office.

> ***Exception:*** Diagnostic and patient treatment areas need not be so marked, provided that a person is charged with the responsibility for protection of employees, patients, and authorized visitors against radiation injuries, and for the execution of Radiation Safety recommendations.

3. The structural shielding requirements of any new installation, or an existing one in which changes are contemplated, shall be discussed with the Radiation Safety staff.

4. An annual, scheduled survey of all radiation producing equipment used on patients shall be made by Radiation Safety personnel. In addition, radiation surveys will be made of all new installations and all existing installations after every change that might increase the radiation hazard

(e.g., replacement of x-ray tube, changes in filtration of beam).

5. Unless measurements indicate that they are not needed, protective aprons shall be worn by the physician, nurse, technician, and all other persons within the room or area who are frequently or habitually exposed to radiation.

6. Dose rates for the beam shall be determined for all units used on human subjects and will be reported to the operator in milliroentgens per milliampere-second or milliroentgens per minute. The "Radiation Exposure Record," Form NIH-378, shall be completed for fluoroscopic and cineradiographic studies and maintained in the patient's record.

7. In the operation of mobile and dental units:
   (a) The operator should stand as far as possible from the tube and patient during exposure, and should wear a protective apron, or step behind an adequate shield.
   (b) An operator, standing at least 6 feet from the tube and patient, should not make more than 5,000 milliampere-seconds of exposure during any one week. Rotation of operators or the use of portable shields is recommended for greater workloads.

8. The hand of the fluoroscopist should never be placed in the useful beam unless the beam is attenuated by the patient and a protective glove of at least 0.25 mm lead equivalent is worn.

9. No person shall be regularly employed to hold patients during exposure, nor shall anyone from the Diagnostic Radiology Department ever be permitted to perform such service. The person holding the patient shall wear protective gloves and a protective apron. No part of this person's body should be in the unattenuated useful beam.

10. If safe use of the installation depends upon mechanical restriction of the orientation of the radiation beam, or upon limitations (voltage, current, time, permanent filter, and maximum aperture) in the output of the unit, then these restricions shall be rigidly followed.

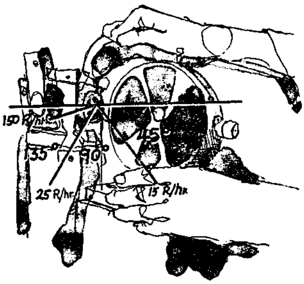
11. Shutter mechanisms and interlocking devices should not be tampered with and shall be inspected at frequent intervals to insure proper operation.

12. All protective devices that may become defective due to use or abuse, such as protective lead aprons or gloves, should be inspected for radiation leakage at least every six months, or whenever the integrity of the equipment is suspect.

13. A manually reset cumulative timing device shall be used which will either indicate elapsed time or turn off the apparatus when the total exposure reaches a certain previously determined limit.

14. In cineradiography, tube currents and potentials are often higher than those used in fluoroscopy. Thus, special care should be taken to limit patient exposure. The exposure rates on these cineradiography units shall be determined during the annual survey.

15. X-ray diffraction equipment can be particularly hazardous because of high exposure rates in the primary beam (e.g., in excess of 500,000 roentgens per minute at the x-ray tube port).



(a) A radiation survey shall be made by the Radiation Safety staff before a new installation is placed in routine operation and whenever changes are made which could adversely affect radiation protection. The equipment shall be frequently inspected for radiation leakage and a radiation survey shall be made at least annually by Radiation Safety personnel.

(b) Appropriate operating procedures and safety measures approved by the Radiation Committee shall be established and followed for these units.

16. Personnel specifically responsible for such equipment shall insure that all workers in the area are monitored in accordance with the requirements for the specific unit.

17. For larger, individually licensed irradiators and accelerators, specific operating and emergency procedures shall be established and posted. All users of this equipment shall operate it in compliance with these posted instructions.

18. All interlocks, visual and audible warning devices, and monitoring equipment shall be inspected for proper operation at six month intervals by Radiation Safety personnel.

Procurement of Radiation Sources

The following procedures for the procurement of radiation sources are intended to insure compliance with the terms and conditions of the license issued by AEC, and the regulations imposed by the Director, NIH:

1. The Radiation Safety Officer must be notified in advance of the procurement of all radiation sources whether ionizing radiation producing machines, AEC-licensable or accelerator-produced isotopes, radium, or other radioactive materials.

2. When the use of radiation sources is planned, the investigator must indicate to the Radiation Committee his training and experience in this area. This is done by submitting one copy of the Form NIH–465 to the Radiation Safety office. When the investigator makes application to the Committee, it is understood that *he accepts the responsibility for complying with the regulations governing the safe use of sources in NIH controlled areas.*

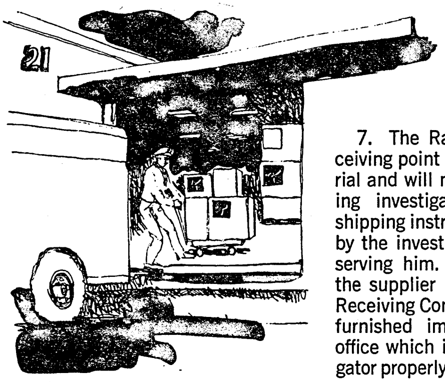
3. Upon notification of approval of his qualifications, the investigator then submits Form NIH–88, "Application for Use of Radioisotopes at the National Institutes of Health," to the Radiation Safety office. The form covers only the quantities specified on a single requisition. The form must be completed regardless of the method of acquisition. In cases other than purchase, the form serves as the required notice to the Radiation Safety office that the receipt of radioactive materials is contemplated through gifts or transfers from any source.

4. Established users of the NIH license may procure radioisotopes under the Telephone Charge Order (TCO) system, provided all conditions of the Small Purchase Procedures Manual (NIH Manual Handbook 2600–103–26.9) are met. Authorized investigators are reminded that: the dollar limit for radioisotopes is $500 and for radionuclides being used under the NIH Broad License delivery must be made within ten (10) days to: *Radiation Safety Officer, National Institutes of Health, Building 21, Radioisotope Laboratory, Bethesda, Maryland 20014.* See Small Purchase Procedures Manual for step-by-step instructions for obtaining radioisotopes by TCO and for list of TCO Account Suppliers.

5. Purchase orders exceeding $500 will be requisitioned in the usual manner by using Form PHS–402–1, "Requisition for Equipment and Sup-

plies," which shall be clearly labeled *"Radioisotope Order."* The requisition must be completed in all normal respects and, in addition, specify that delivery be made to the *Radiation Safety Officer, National Institutes of Health, Building 21, Radioisotope Laboratory, Bethesda, Maryland 20014.* The requisition and accompanying Form NIH–88 are routed through Radiation Safety, Bldg. 21, to the Procurement Section, Bldg. 13.

6. The purchase order will then be prepared by the Procurement Section, Materiel Management, and routed through the Radiation Safety office for final approval. The Radiation Safety Officer will indicate approval and place the AEC license number on the purchase order and forward it to the supplier.



7. The Radiation Safety office will be the receiving point on the NIH reservation for such material and will make the actual delivery to the ordering investigator. Any changes in the original shipping instructions should be furnished this office by the investigator or the Institute ordering office serving him. Shipping information received from the supplier by the Procurement Section and the Receiving Control Reports Section, Bldg. 13, will be furnished immediately to the Radiation Safety office which in turn will keep the ordering investigator properly informed.

8. In the case of ionizing radiation producing machines such as x-ray units, Van de Graaff generators, etc., the notification is made on Form NIH–1912, "Request for Authorization to Purchase and Use Radiation Producing Machinery or Equipment". The filing of Training and Experience Form NIH–465 may or may not be required by the Radiation Committee depending on the device(s), its complexity and the proposed uses. Consult with the Radiation Safety Officer concerning this Training and Experience requirement. The equipment is then requisitioned in the usual manner using Form PHS–402–1.

Shipping Radioactive Materials

1. When radioactive material is to be shipped from NIH, the shipper must notify the Radiation Safety office instead of the Shipping and Receiving Section. The Radiation Safety staff will pick up these shipments on telephone request. The usual NIH shipping request Form NIH 1884 is to be prepared and will accompany the container. Under item 7 of this form the description of articles must include radionuclide, chemical form, and activity (in μCi or mCi).

2. The recipient of any material to be shipped from NIH must provide evidence of an AEC (or agreement state*) license by furnishing a copy of his license to the Radiation Safety office before shipment can be made. Noncompliance with this requirement is a violation of the Atomic Energy Act and is subject to criminal prosecution as well as denial to NIH of further AEC-controlled radioisotopes. Check first with the Radiation Safety staff by phone to see if the recipient's license is already on file. If not, then request a copy from the recipient in order to fulfill this requirement.

3. The investigator is reminded that the NIH specific license of broad scope *covers only the Bethesda reservation and the Auburn Building.* Materials transported by the investigator to other installations must be transferred to the respective licensees in that area as in paragraph 2 above and in a manner complying with applicable AEC and/or Department of Transportation regulations.

4. When an empty radioisotope container is to be returned to the supplier, the ordering investigator must notify the Radiation Safety office, who will certify that it is free of contamination. The container may then be returned through normal channels. Promptness in returning the container is urged. Conditions of purchase usually require that such containers will be returned within a specified period of time.

---

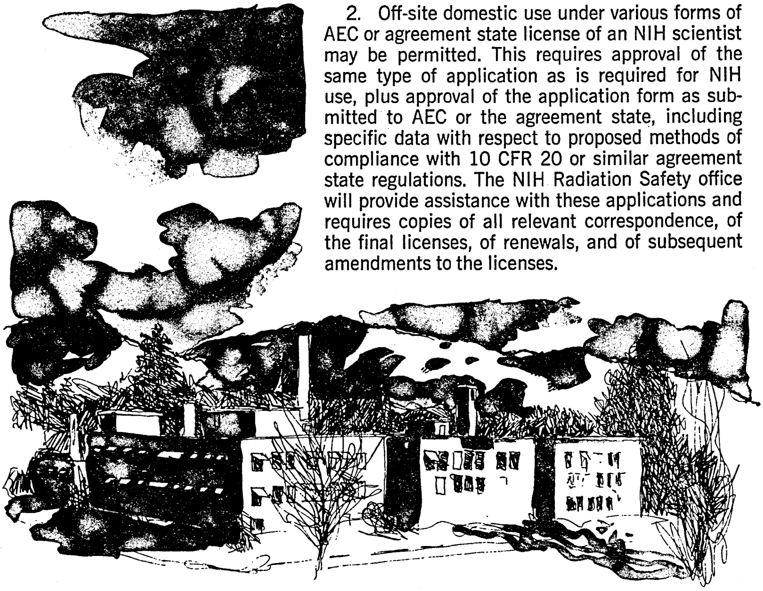
*Agreement States: Those states that have entered into agreements with the AEC for the control of radioactive material.

Off-Site Use of Isotopes by NIH Staff

As specified in NIH Manual Issuance 1344, NIH investigators working with radioactive materials and radiation producing devices will comply with the following:

1. All off-site† uses of radioisotopes, domestic or foreign, under "generally licensed quantities" (10 CFR 31.100) or individual AEC or agreement state license should be subject to the same scientific review and approval by the Radiation Committee as prevails for in-house use.

2. Off-site domestic use under various forms of AEC or agreement state license of an NIH scientist may be permitted. This requires approval of the same type of application as is required for NIH use, plus approval of the application form as submitted to AEC or the agreement state, including specific data with respect to proposed methods of compliance with 10 CFR 20 or similar agreement state regulations. The NIH Radiation Safety office will provide assistance with these applications and requires copies of all relevant correspondence, of the final licenses, of renewals, and of subsequent amendments to the licenses.



3. Off-site foreign use may be authorized following compliance with paragraph (1) and receipt by the Radiation Committee of an acceptable statement indicating the full knowledge and agreement of an appropriate authority in the host country.

---

†Off-site: All research locations other than the NIH reservation and the Auburn Building (Bethesda) where NIH personnel are assigned.

4. All NIH scientists using radioisotopes under any circumstances in off-site locations, domestic or foreign, must use NIH personnel monitoring devices when indicated or be under an equivalent monitoring program acceptable to and reporting to the NIH Radiation Safety office.

5. The NIH Radiation Committee and Radiation Safety office are authorized to intervene and apply the applicable NIH regulations to off-site uses of other sources of ionizing radiations employed by NIH personnel.

6. Users of radioisotopes authorized and procured under the NIH Broad AEC License are reminded that this license is specific for the NIH *Bethesda reservation and Auburn Building.* This means that the transfer of radioisotopes from these locations to off-site premises requires clearance through the NIH Radiation Safety office. Transfers of radioisotopes from off-site locations to NIH must be made in accordance with the requirements of "Procurement of Radiation Sources."

GLOSSARY

ABSORBED DOSE: The amount of energy imparted to matter by ionizing radiation per unit mass of irradiated material. (See Rad)

ABSORPTION: The phenomenon by which radiation imparts some or all of its energy to any material through which it passes.

ACTIVITY: The number of nuclear disintegrations occurring in a given quantity of material per unit time. (See Curie)

ALPHA PARTICLE: A strongly ionizing particle emitted from the nucleus during radioactive decay having a mass and charge equal in magnitude to a helium nucleus, consisting of 2 protons and 2 neutrons with a double positive charge.

ALPHA RAY: A stream of fast-moving helium nuclei (alpha particles), a strongly ionizing and weakly penetrating radiation.

ANNIHILATION (Electron): An interaction between a positive and negative electron; their energy, including rest energy, being converted into electromagnetic radiation (annihilation radiation).

ATOM: Smallest particle of an element which is capable of entering into a chemical reaction.

AUTORADIOGRAPH: Record of radiation from radioactive material in an object, made by placing the object in close proximity to a photographic emulsion.

BACKGROUND RADIATION: Ionizing radiation arising from radioactive material other than the one directly under consideration. Background radiation due to cosmic rays and natural radioactivity is always present. There may also be background radiation due to the presence of radioactive substances in other parts of the building, in the building material itself, etc.

BETA PARTICLE: Charged particle emitted from the nucleus of an atom, having a mass and charge equal in magnitude to that of the electron.

BETA RAY: A stream of high speed electrons or positrons of nuclear origin more penetrating but less ionizing than alpha rays.

BREMSSTRAHLUNG: Electromagnetic (x-ray) radiation associated with the deceleration of charged particles passing through matter. Usually associated with energetic beta emitters, e.g., phosphorus-32.

CALIBRATION: Determination of variation from standard, or accuracy, of a measuring instrument to ascertain necessary correction factors.

CONTAMINATION, RADIOACTIVE: Deposition of radioactive material in any place where it is not desired, and particularly in any place where its presence may be harmful. The harm may be in vitiating the validity of an experiment or a procedure, or in actually being a source of excessive exposure to personnel.

CARRIER FREE: An adjective applied to one or more radioactive iostopes of an element in minute quantity, essentially undiluted with stable isotope carrier.

COUNT (Radiation Measurements): The external indication of a device designed to enumerate ionizing events. It may refer to a single detected event or to the total registered in a given period of time. The term is often erroneously used to designate a disintegration, ionizing event, or voltage pulse.

CRITICAL ORGAN: That organ or tissue, the irradiation of which will result in the greatest hazard to the health of the individual or his descendants.

CURIE: The quantity of any radioactive material in which the number of disintegrations is 3.700×10^{10} per second. Abbrevated Ci.

> Millicurie: One-thousandth of a curie (3.7×10^{7} disintegrations per second). Abbreviated mCi. Microcurie: One millionth of a curie (3.7×10^{4} disintegrations per second). Abbreviated μCi. Picocurie: One millionth of a microcurie (3.7×10^{-2} disintegrations per second or 2.22 disintegrations per minute). Abbreviated pCi.

DECAY, RADIOACTIVE: Disintegration of the nucleus of an unstable nuclide by the spontaneous emission of charged particles and/or photons.

DOSE: A general term denoting the quantity of radiation or energy absorbed in a specified mass. For special purposes it must be appropriately qualified, e.g., absorbed dose.

DOSE, ABSORBED: The energy imparted to matter by ionizing radiation per unit mass of irradiated material at the place of interest. The unit of absorbed dose is the rad, which is 100 ergs/gram.

DOSE EQUIVALENT: A quantity used in radiation protection expressing all radiation on a common scale for calculating the effective absorbed dose. The unit of dose equivalent is the rem, which is numerically equal to the absorbed dose in rads multiplied by certain modifying factors such as the quality factor, the distribution factor, etc.

EFFICIENCY (Counters): A measure of the probability that a count will be recorded when radiation is incident on a detector. Usage varies considerably so it is well to make sure which factors (window, transmission, sensitive volume, energy dependence, etc.) are included in a given case.

ELECTRON: Negatively charged elementary particle which is a constituent of every neutral atom. Its unit of negative electricity equals 4.8×10^{-10} electrostatic units or 1.6×10^{-19} coulombs. Its mass is 0.00549 atomic mass units.

ELECTRON CAPTURE: A mode of radioactive decay involving the capture of an orbital electron by its nucleus. Capture from the particular electron shell is designated as "K-electron capture," "L-electron capture," etc.

ELECTRON VOLT: A unit of energy equivalent to the amount of energy gained by an electron in passing through a potential difference of 1 volt. Abbreviated eV. Larger multiple units of the electron volt frequently used are: keV for thousand or kiloelectron volts, MeV for million electron volts and BeV for billion electron volts.

EXPOSURE: A measure of the ionization produced in air by x or gamma radiation. It is the sum of the electrical charges on all ions of one sign produced in air when all electrons liberated by photons in a volume element of air are completely stopped in air, divided by the mass of air in the volume element. The special unit of exposure is the roentgen.

FILM BADGE: A packet of photographic film used for the approximate measurement of radiation exposure for personnel monitoring purposes. The badge may contain two or more films of differing sensitivity, and it may contain filters which shield parts of the film from certain types of radiation.

FILTER (Radiology), PRIMARY: A sheet of material, usually metal, placed in a beam of radiation to remove, as far as possible, the less penetrating components of the beam. **SECONDARY:** A sheet of material of lower atomic number, relative to that of the primary filter, placed in the filtered beam of radiation to remove characteristic radiation produced by the primary filter.

GAMMA RAY: Very penerating electromagnetic radiation of nuclear origin. Except for origin, identical to x-ray.

GEIGER-MUELLER (G-M) COUNTER: Highly sensitive gas-filled detector and associated circuitry used for radiation detection and measurement.

GENETIC EFFECT OF RADIATION: Inheritable changes, chiefly mutations, produced by the absorption of ionizing radiations. On the basis of present knowledge these effects are purely additive, and there is no recovery.

HALF-LIFE, BIOLOGICAL: The time required for the body to eliminate one-half of an administered dose of any substance by the regular processes of elimination. This time is approximately the same for both stable and radioactive isotopes of a particular element.

HALF-LIFE, EFFECTIVE: Time required for a radioactive nuclide in a system to be diminished 50 percent as a result of the combined action of radioactive decay and biological elimination.

$$\text{Effective half-life} = \frac{\text{Biological half-life} \times \text{Radioactive half-life}}{\text{Biological half-life} + \text{Radioactive half-life}}$$

HALF-LIFE, RADIOACTIVE: Time required for a radioactive substance to lose 50 percent of its activity by decay. Each radionuclide has a unique half-life.

HALF VALUE LAYER (Half thickness): The thickness of any specified material necessary to reduce the intensity of an x-ray or gamma ray beam to one-half its original value.

HEALTH PHYSICS: A term in common use for that branch of radiological science dealing with the protection of personnel from harmful effects of ionizing radiation.

INVERSE SQUARE LAW: The intensity of radiation at any distance from a point source varies inversely as the square of that distance. For example: If the radiation exposure is 100 R/hr at 1 inch from a source, the exposure will be 0.01 R/hr at 100 inches.

ION: Atomic particle, atom, or chemical radical bearing an electrical charge, either negative or positive.

IONIZATION: The process by which a neutral atom or molecule acquires either a positive or a negative charge.

IONIZATION CHAMBER: An instrument designed to measure the quantity of ionizing radiation in terms of the charge of electricity associated with ions produced within a defined volume.

IONIZATION, SPECIFIC: The number of ion pairs per unit length of path of ionizing radiation in a medium; e.g., per centimeter of air or per micron of tissue.

IONIZING RADIATION: Any electromagnetic or particulate radiation capable of producing ions, directly or indirectly, in its passage through matter.

ISOTOPES: Nuclides having the same number of protons in their nuclei, and hence having the same atomic number, but differing in the number of neutrons, and therefore in the mass number. Almost identical chemical properties exist between isotopes of a particular element.

LABELED COMPOUND: A compound consisting, in part, of labeled molecules. By observations of radioactivity or isotopic composition this compound or it fragments may be followed through physical, chemical or biological processes.

MAXIMUM PERMISSIBLE DOSE (MPD): Maximum dose of radiation which may be received by persons working with ionizing radiation, which will produce no detectable damage over the normal life span.

MILLIROENTGEN (mR): A submultiple of the roentgen equal to one one-thousandth (1/1000th) of a roentgen. (See Roentgen)

MONITORING, RADIOLOGICAL: Periodic or continuous determination of the amount of ionizing radiation or radioactive contamination present in an occupied region as a safety measure for purposes of health protection.

Area Monitoring: Routine monitoring of the level of radiation or of radioactive contamination of any particular area, building, room or equipment.

Personnel Monitoring: Monitoring any part of an individual, his breath, excretions, or any part of his clothing. (See Radiological Survey)

NEUTRON: Elementary particle with a mass approximately the same as that of a hydrogen atom and electrically neutral. It has a half-life in minutes and decays in a free state into a proton and an electron.

NUCLIDE: A species of atom characterized by its mass number, atomic number, and energy state of its nucleus, provided that the atom is capable of existing for a measurable time.

PROTECTIVE BARRIERS: Barriers of radiation absorbing material, such as lead, concrete, plaster, and plastic, that are used to reduce radiation exposure.

Protective Barriers, Primary: Barriers sufficient to attenuate the useful beam to the required degree.

Protective Barriers, Secondary: Barriers sufficient to attenuate stray or scattered radiation to the required degee.

RADIATION: 1. The emission and propagation of energy through space or through a material medium in the form of waves; for instance, the emission and propagation of electromagnetic waves, or of sound and elastic waves. 2. The energy propagated through a material medium as waves; for example, energy in the form of electromagnetic waves or of elastic waves. The term "radiation" or "radiant energy," when unqualified, usually refers to electromagnetic radiation. Such radiation commonly is classified according to frequency as Hertzian, infrared, visible (light), ultra-violet, x-ray, and gamma ray. 3. By extension, corpuscular emissions, such as alpha and beta radiation, or rays of mixed or unknown type, as cosmic radiation.

RADIOLOGICAL SURVEY: Evaluation of the radiation hazards incident to the production, use or existence of radioactive materials or other sources of radiation under a specific set of conditions. Such evaluation customarily includes a physical survey of the disposition of materials and equipment, measurements or estimates of the levels of radiation that may be involved, and a sufficient knowledge of processes using or affecting these materials to predict hazards resulting from expected or possible changes in materials or equipment.

RADIOTOXICITY: Term referring to the potential of an isotope to cause damage to living tissue by absorption of energy from the disintegration of the radioactive material introduced into the body.

RELATIVE BIOLOGICAL EFFECTIVENESS (RBE): For a particular living organism or part of an organism, the ratio of the absorbed dose of a reference radiation that produces a specified biological effect to the absorbed dose of the radiation of interest that produces the same biological effect.

REM: The special unit of dose equivalent. The dose equivalent in rems is numerically equal to the absorbed dose in rads multiplied by the quality factor, distribution factor, and any other necessary modifying factors.

ROENTGEN (R): The quantity of x or gamma radiation such that the associated corpuscular emission per 0.001293 grams of dry air produces, in air, ions carrying one electrostatic unit of quantity of electricity of either sign. The roentgen is the special unit of exposure.

SCINTILLATION COUNTER: A counter in which light flashes produced in a scintillator by ionizing radiation are converted into electrical pulses by a photomultiplier tube.

SHIELDING MATERIAL: Any material which is used to absorb radiation and thus effectively reduce the intensity of radiation, and in some cases eliminate it. Lead, concrete, aluminum, water, and plastic are examples of commonly used shielding material.

SMEAR (Smear or Swipe Test): A procedure in which a swab, e.g., a circle of filter paper, is rubbed on a surface and its radioactivity measured to determine if the surface is contaminated with loose radioactive material.

SPECIFIC ACTIVITY: Total radioactivity of a given nuclide per gram of a compound, element or radioactive nuclide.

TRACER, ISOTOPIC: The isotope or nonnatural mixture of isotopes of an element which may be incorporated into a sample to make possible observation of the course of that element, alone or in combination, through a chemical, biological, or physical process. The observations may be made by measurement of radioactivity or of isotopic abundance.

THERMOLUMINESCENT DOSIMETER: A dosimeter made of certain crystalline material which is capable of both storing a fraction of absorbed ionizing radiation and releasing this energy in the form of visible photons when heated. The amount of light released can be used as a measure of radiation exposure to these crystals.

X-RAYS: Penetrating electromagnetic radiations having wave lengths shorter than those of visible light. They are usually produced by bombarding a metallic target with fast electrons in a high vacuum. In nuclear reactions it is customary to refer to photons originating in the nucleus as gamma rays, and those originating in the extranuclear part of the atom as x-rays. These rays are sometimes called roentgen rays after their discoverer, W. C. Roentgen.

GUIDELINES FOR MAXIMUM PERMISSIBLE DOSES FOR NIH PERSONNEL

Organ	Dose in mrem			
	Year	Quarter	Month	Week
Whole Body (Including Gonads, Lens of Eye, Red Bone Marrow)	5,000	1,250	400	100
Forearms, Hands, Feet and Ankles	75,000	18,750	6,250	1,500
Skin of Whole Body	30,000	7,500	2,500	650
Pregnant Women or Employees Under 18 Years of Age	500	125	40	10

For information on specific organs or tissues not listed, consult with Radiation Committee or Radiation Safety Officer.

CLASSIFICATION OF ISOTOPES ACCORDING TO RELATIVE RADIOTOXICITY PER UNIT ACTIVITY

(Based on Published Data and NIH User Experience)

Class 1 (very high toxicity)

Sr-90 + Y-90, *Pb-210 + Bi-210(Ra D + E), Po-210, At-211, *Ra-226 + 55% *daughter products, Ac-227, *U-233, Pu-239, *Am-241, Cm-242, plus other transuranium isotopes.

Class 2 (high toxicity)

Ca-45, *Ca-47, *Fe-59, *Sr-85, Sr-89, Y-91, *Ru-106 + Rh-106, *I-125, *I-131, *Ba-140 + *La-140, Ce-144 + *Pr-144, Sm-151, *Eu-154, *Tm-170, *Hg-203, *Th-234 + *Pa-234, *natural uranium.

Class 3 (moderate toxicity)

*Na-22, *Na-24, P-32, P-33, S-35, Cl-36, *K-42, *Sc-46, *Sc-47, *Sc-48, *V-48, *Mn-52, *Mn-54, *Mn-56, Fe-55, *Co-57, *Co-58, *Co-60, Ni-59, *Cu-64, *Cu-67, *Zn-65, *Ga-67, *Ga-72, *As-74, *As-76, *Br-82, *Kr-85, *Rb-84, *Rb-86, *Zr-95 + *Nb-95, *Nb-95, *Mo-99, Tc-98, *Rh-105, Pd-103 + Rh-103, *Ag-105, *Ag-111, Cd-109 + *Ag-109, *Sn-113, *Te-127, *Te-129, *I-132, *Xe-133, *Cs-137 + *Ba-137, *La-140, Pr-143, Pm-147, *Ho-166, *Lu-177, *Ta-182, *W-181, *Re-183, Ir-190, *Ir-192, Pt-191, *Pt-193, *Au-196, *Au-198, *Au-199, Tl-200, Tl-202, Tl-204, *Pb-203, *Hg-197.

Class 4 (slight toxicity)

H-3, Be-7, C-14, *F-18, *Cr-51, Ge-71, *Sr-87m, *Tc-99m, *Tl-201.

*Gamma emitter and/or associated photon emitter.

GUIDELINES FOR MAXIMUM ACTIVITIES IN NIH LABORATORIES

Radiotoxicity of Isotopes	Minimum Significant Quantity Utilized	Typical NIH Laboratory	Isotope Laboratory Building 21 (1)
Very high	0.1 μCi	10 μCi or less	10 μCi–10 mCi
High	1.0 μCi	100 μCi or less	100 μCi–100 mCi
Moderate	10 μCi	1 mCi or less	1 mCi–1 Ci
Slight	100 μCi	10 mCi or less	10 mCi–10 Ci

Modifying factors should be applied to the quantities indicated in the last 2 columns of the above table, according to the complexity of the procedures to be followed. The following factors are suggested but due regard should be paid to the circumstances affecting individual cases.

Procedure	*Modifying factor*
Storage (stock solutions)	× 100
Very simple wet operations	× 10
Normal chemical operations	× 1
Complex wet operations with risk of spills	× 0.1
Simple dry operations	× 0.1
Dry and dusty operations	× 0.01

(1) With proper documentation of experimental protocol and with approval of the Radiation Committee, investigators may be permitted to use these quantities in NIH laboratories outside Building 21. With similar documentation, activities exceeding these maximum quantities may be approved for use in Building 21 only.

SELECTED PROPERTIES OF MOST FREQUENTLY ORDERED RADIONUCLIDES

Nuclide	Maximum Beta Energy (MeV)	Gamma Energy (MeV)	Iγ mR/hr/mCi at 1 m	MPBB (μCi)	Critical Organ	Half-Life	
						Radioactive	Biological (days)
^{3}H	0.0186			1000	Body Tissue	12.26y	12
^{14}C	0.156			300	Fat	5730y	12
^{24}Na	1.389	1.369 (100%) 2.754 (100%)	1.84	7	Total Body	14.96h	11
^{32}P	1.710			6	Bone	14.28d	1155
^{33}P	0.248			40	Bone	24.4d	1155
^{35}S	0.167			90	Testis	87.9d	623
^{51}Cr		0.32(9%)	0.016	800	Total Body	27.8d	616
^{125}I		28 keV average (143%)	0.07	1.6	Thyroid	60.2d	138
^{131}I	0.606	0.637 (6.8%) 0.364 (82%)	0.22	0.7	Thyroid	8.05d	138

Column (4), Iγ Milliroentgens per hour at 1 meter from 1 millicurie.

Column (5), Maximum Permissible Body Burden (MPBB). The amount of the isotope maintained in the body which will deliver the maximum permissible dose equivalent rate to the limiting organ. The value given is for material that has been absorbed by the blood stream and deposited in the body. The lung or gastrointestinal tract may be more limiting for continued exposure to chemical forms that are not readily absorbed.

Column (6), Critical Organ. The organ that receives the highest dose equivalent relative to its maximum permissible dose equivalent from a sustained intake (see discussion of Column 5). The maximum permissible body burden may be identical for several organs. Then, the organ with the smallest maximum permissible dose equivalent or the organ affected by most other radioactive materials was chosen.

Column (7), Radioactive Half-Life. Present best value, obtained from "Table of Isotopes—6th Edition" by C. M. Lederer, J. M. Hollander, and I. Perlman, John Wiley & Sons, New York, 1967. The abbreviations used here are: s, second; m, minute; h, hour; d, day; and y, year.

Column (8), Biological Half-Life. The time required for one-half of the stable element to be removed from the critical organ by biological processes, as listed by the ICRP. The actual half-time of elimination depends also on the half-life of the isotope. The "effective half-life" in the critical organ (T_{Eff}) is given by $T_{Eff} = \frac{T_R T_B}{T_R + T_B}$ where T_R is the radioactive half-life and T_B is the biological half-life.

Rules of Thumb

Beta Particles

a. Beta particles of at least 70 keV energy are required to penetrate the nominal protective layer of the skin (7 mg/cm^2 or 0.07 mm).

b. The average energy of a beta-ray spectrum is approximately one-third the maximum energy.

c. The range of beta particles in air is $\sim$ 12 ft/MeV. (Maximum range of ^{32}P beta is 1.71 MeV $\times$ 12 ft/Mev $\cong$ 20 ft).

d. The dose rate in rads per hour in a solution by a beta emitter is $1.12\ EC/\rho$, where E is the average beta energy per disintegration in MeV, C is the concentration in microcuries per cubic centimeter, and ρ is the density of the medium in grams per cubic centimeter. The dose rate at the surface of the solution is one-half the value given by this relation. (For ^{32}P average energy of approximately 0.7 MeV, the dose rate from 1 μCi/cm^3 (in water) is 1.48 rads/hr).

e. The surface dose rate through the nominal protective layer of skin (7 mg/cm^2) from a uniform thin deposition of 1 μCi/cm^2 is about 9 rads/hour for energies above about 0.6 MeV. Note that in a thin layer, the beta dose rate exceeds the gamma dose rate, for equal energies released, by about a factor of 100.

f. For a point source of beta radiation (neglecting self and air absorption) of strength mCi millicuries, the dose rate at 1 cm is approximately equal to 200 $\times$ mCi rads/hour and varies only slowly with beta energy. Dose rate for 1 mCi ^{32}P at 1 cm is approximately 200 rads/hour.

Gamma Rays

a. For a point source gamma emitter with energies between 0.07 and 4 MeV, the exposure rate (mR/hr) within ± 20% at 1 foot is 6 × mCi × E × n, where mCi is the number of millicuries; E, the energy in MeV; and n, the number of gammas per disintegration.

b. The dose rate to tissue in rads per hour in an infinite medium uniformly contaminated by a gamma emitter is 2.12 EC/ρ, where C is the number of microcuries per cubic centimeter, E is the average gamma energy per disintegration in MeV, and ρ is the density of the medium. At the surface of a large body, the dose rate is about half of this.

X-Ray

a. The exposure rate at 2 feet from diagnostic x-ray equipment operated at 100 kVp and 100 milliamperes is approximately 2.3 roentgens/second.

b. Exposure rate at the fluoroscopy table with tube potential at 80 kVp and tube current of 1 milliampere should not exceed 2.1 roentgens/minute.

c. Scattered radiation can be as penetrating as the primary beam.

X-Ray Diffraction

a. The x-ray beam intensities from the primary beam can be as much as 400,000 R/min.

b. Scattered radiation 10 cm from the points of scatter about the x-ray tube head has been measured in the order of 150 R/hr.

c. The threshold dose sufficient to produce skin erythema is 300 to 400 roentgens.

d. The minimum cataractogenic single dose is 200 rads, while a dose of 750 rads exhibits a high incidence of cataract formation.

Miscellaneous

a. The activity of any radionuclide is reduced to less than 1% after 7 half-lives (i.e., 2^{-7} = 0.8%).

b. For material with a half-life greater than six days, the change in activity in 24 hours will be less than 10%.

MIRD Absorbed Dose Calculations

The following are examples of the equations and calculations necessary to estimate absorbed dose according to the schema developed and published by the Medical Internal Radiation Dose (MIRD) Committee of the Society of Nuclear Medicine. Pamphlets containing the required data may be obtained by writing: MIRD Committee, Society of Nuclear Medicine, 211 E. 43rd Street, New York, New York 10017. A limited number of copies are available for short term loan from the Radiation Safety office. Reminder: when using the MIRD method, it is most important to keep all quantities in the specified units.

A. General Equation

$$\bar{D}(v_2 \leftarrow v_1) = \frac{\tilde{A}}{m} \sum_i \Delta_i \phi_i (v_2 \leftarrow v_1)$$

where $\bar{D}$ = mean absorbed dose (rads)
$(v_2 \leftarrow v_1)$ = target volume (v_2) absorbing radiation from source volume (v_1)
$\tilde{A}$ = cumulated activity (μCi-h)
m = mass of target organ (g)
Δ = equilibrium dose constant (g-rad/μCi-h)
i = subscript symbol for all types of radiation
ϕ = absorbed fraction (dimensionless)

B. Other Important Equations

1. $\tilde{A} = A_0 \int_{t_0}^{t} \exp(-0.693t/T_{eff})\, dt$

where A_0 = initial activity in source volume (μCi)
t = time (h)
T_{eff} = effective half-life (h)

2. $\frac{1}{T_{eff}} = \frac{1}{T_{bio}} + \frac{1}{T_{phy}}$

where T_{bio} = biological half-life (h) of isotope in the source volume
T_{phy} = physical half-life (h)

3. For complete disintegration of the isotope:
$\tilde{A} = A_0\,(1.44 \times T_{eff})$

4. For non-pentrating radiation:
$\phi_{n-p}(v_1 \longleftrightarrow v_1) = 1$
$\phi_{n-p}(v_2 \leftarrow v_1) = 0$, if $v_2 \neq v_1$
where $_{n-p}$ = the subscript indicating non-penetrating radiations
$(v_1 \longleftrightarrow v_1)$ = target organ and source are the same volumes

5. For penetrating radiation:
ϕ is dependent upon the geometry of the system and energies of the radiation(s) and can be found in MIRD Pamphlet 5. If necessary, plot values of ϕ for specific source and target organs vs. energy.

C. Specific Example

The following example is given solely to demonstrate the method of calculation and does not necessarily indicate that the target organs selected will receive the highest absorbed doses.

Example: 0.1 mCi ^{24}Na is administered orally and is excreted exponentially from the stomach with a three hour half-time. What is the absorbed dose to the stomach? to the total body? (Simplifying assumption: idealized condition with no absorption of ^{24}Na from the stomach into the body.)

1. Necessary Information on ^{24}Na in the Stomach
   a. Biological half-life (T_{bio}) = 3 h (given)
   b. Physical half-life (T_{phy}) = 15 h (from MIRD Pamphlet 4, p. 16)
   c. Calculated effective half-life:

$$\frac{1}{T_{eff}} = \frac{1}{3} + \frac{1}{15};\ T_{eff} = 2.5\text{ h}$$

   d. Decay data (from MIRD Pamphlet 4, p. 16)

Radiation Type	Energy (MeV)	Δ_i $\left[\frac{\text{g-rad}}{\mu\text{Ci-h}}\right]$
Beta-1	0.5547	1.1803
Gamma-1	1.3685	2.9149
Gamma-2	2.7539	5.8599

   e. Biological data (from MIRD Pamphlet 5, Table 1, p. 8)
      1) Source organ: stomach, 402 g
      2) Target organ: stomach, 402 g
      3) Target organ: total body, 70,036 g

2. Calculation of Dose from Stomach (v_1) to Stomach (v_1)
   a. Calculation of $\sum_i \Delta_i\phi_i$
      1) Non-penetrating radiation

$\phi_{n-p}(v_1 \longleftrightarrow v_1) = 1$

$\sum_{n-p}\Delta\phi = 1 \times 1.1803 = 1.1803$ g-rad/μCi-h

      2) Penetrating radiation

Values of ϕ for penetrating radiation are given in MIRD Pamphlet 5, p. 19.

$\phi_{\gamma_1} = 0.09$

$\phi_{\gamma_2} = 0.072$

$\sum\Delta_{\gamma_1}\phi_{\gamma_1} = 2.9149 \times 0.09 = 0.2623$

$\sum\Delta_{\gamma_2}\phi_{\gamma_2} = 5.8599 \times 0.072 = 0.4219$

$\sum_p\Delta\phi = 0.2623 + 0.4219 = 0.6842$ g-rad/μCi-h

      3) Total $\sum\Delta\phi$

$\sum_{n-p}\Delta\phi + \sum_p\Delta\phi = 1.1803 + 0.6842 = 1.8645$ g-rad/μCi-h

b. Calculation of Cumulated Activity

$\tilde{A} = A_o(1.44 \times T_{eff}) = 100(1.44 \times 2.5) = 360\ \mu\text{Ci-h}$

c. Calculation of Dose to the Stomach from Source in the Stomach

$$\bar{D} = \frac{\tilde{A}}{m}\sum_i \Delta_i\phi_i = \frac{360\ \mu\text{Ci-h}}{402\ \text{g}} \times 1.8645\ \frac{\text{g-rad}}{\mu\text{Ci-h}} = 1.669\ \text{rads}$$

3. Calculation of Dose from the Stomach (v_1) to the Total Body (v_2)

a. Calculation of $\sum_i \Delta_i\phi_i$

1) Non-penetrating radiation

$\phi_{n-p}\ (v_2 \leftarrow v_1) = 0$; thus, no contribution to absorbed dose to total body

2) Penetrating radiation

Values of ϕ for penetrating radiation are given in MIRD Pamphlet 5, p. 19.

$\phi_{\gamma_1} = 0.37$

$\phi_{\gamma_2} = 0.33$

$\sum \Delta_{\gamma_1}\phi_{\gamma_1} = 2.9149 \times 0.37 = 1.0785$

$\sum \Delta_{\gamma_2}\phi_{\gamma_2} = 5.8599 \times 0.33 = 1.9338$

$\sum_p \Delta\phi = 1.0785 + 1.9338 = 3.0122$ g-rad/μCi-h

3) Total $\sum \Delta\phi$

$\sum_{n-p} \Delta\phi + \sum_p \Delta\phi = 0 + 3.0122 = 3.0122$ g-rad/μCi-h

b. Calculation of Cumulated Activity

Same as above: 360 μCi-h.

c. Calculation of Dose to the Total Body from the Stomach

$$\bar{D} = \frac{\tilde{A}}{m}\sum_i \Delta_i\phi_i = \frac{360\ \mu\text{Ci--h}}{70{,}036\ \text{g}} \times 3.0122\ \frac{\text{g--rad}}{\mu\text{Ci--h}} = 0.015\ \text{rads}$$

4. Summary of Dose Calculations

100 μCi ^{24}Na; Source Organ: Stomach

Target Organ	Absorbed Dose (rads)
Stomach	1.669
Total Body	0.015

Office of Telecommunications Policy,
Executive Office of the President,
Washington, D.C., June 10, 1977.

Hon. Adlai E. Stevenson,
Hon. Wendell H. Ford,
Committee on Commerce, Science, and Transportation,
U.S. Senate, Washington, D.C.

Dear Senators: We are pleased to supply the following information in response to your letter of May 19, 1977, in connection with the Senate Committee on Commerce, Science, and Transportation hearings to review and evaluate federal radiation research and regulatory programs.

The activities of this office, relevant to your inquiry, are in the area of nonionizing radiation. They stem from our statutory responsibilities for the use of the radio-frequency spectrum by the Federal Government for telecommunications as set forth in Executive Order 11556 of September 4, 1970. OTP is also responsible for advising the President on national policy in the telecommunications field and for coordination of telecommunications activities and associated research. An integral part of these responsibilities is to ensure that the use of nonionizing electromagnetic energy does not harm either man or his environment or cause interference with other electronic equipment. It is important also to ensure that the many vital and beneficial services derived from the use of the spectrum are not unnecessarily curtailed or impaired.

In 1968, OTP initiated efforts to provide a focal point and review in this area and established the Electromagnetic Radiation Management Advisory Council (ERMAC) consisting of individuals with expertise in the various pertinent technical disciplines, to advise us on possible unintended or undesirable "side effects" which might be associated with the use of electromagnetic radiation. As a result of the ERMAC's activities, OTP recommended a coordinated Federal program to assess the biological effects of nonionizing radiation (0 Hz–300 GHz). This multiagency program is comprised of the independently funded activities of those agencies concerned with the use of electromagnetic radiation and/or health and the environment (e.g. the Department of Health, Education, and Welfare, the Environment Protection Agency, and the Department of Defense). Each agency is responsible for determining and controlling the specifics of its research efforts, taking into consideration program needs and recommended funding levels. OTP overviews, coordinates and provides a focal point and a forum for program efforts. An interdepartmental working group assists in providing intragovernmental coordination and the exchange of information. The ERMAC provides advice, recommendations, and review of program activities.

With regard to your request for fiscal information (see enclosure 1), it is important to note that this Office, in its coordinating and overview role, does not fund research or provide funds to participating agencies. Expenditures shown are for efforts which support the coordination process or provide information to the research community.

The responses to the specific questions posed in your letter are contained in enclosure 2.

We appreciate the opportunity to contribute to your review of Federal radiation research and regulatory programs and would be pleased to provide any additional information or assistance required.

Sincerely,

William J. Thaler.

Enclosures.

Footnote Explanations

1. All activities are associated with OTP's program coordination and overview role.

2. Estimated total manpower in manyears (MY). This is a composite figure including staff, full and part time, administration/supervision and secretarial support. Since 1973 it has included one full time military detail and, in 1977, one MY support from DOC/OT was added.

3. Contracts to provide coordination and technical support including a computerized information system on biological effects of non-ionizing EMR (in $K).

4. Includes personnel cost based on an estimated averaged MY @ $30K (see note 2), contracts, and approximate costs for ERMAC - consists of travel to attend meetings only.

ENCLOSURE 2

The following are responses to the specific questions posed in your letter (numbers refer to your question number):

1. Reorganization Plan No. 1 of April 29, 1970, established OTP to replace the former Office of Telecommunications Management and, as amplified by Executive Order 11556 of September 1970, broadened the responsibility for, and gave increased impetus to, the office's activities in the nonionizing electromagnetic radiation area. OTP is specifically charged to:

"(b) Develop and set forth plans * * * programs with respect to telecommunications that will promote public interest * * *

"(e) Coordinate the telecommunications activities of the executive branch and formulate policies and standards, therefor, including * * * spectrum use * * *

"(g) Review telecommunications research * * * by Federal agencies. Identify competing, overlapping, duplicative or inefficient programs, and make recommendations to appropriate agency officials and to the Director of the Office of Management and Budget * * *"

Because OTP's activities involve coordinating all relevant Federal activities, it is necessary to incorporate active or interested participants as missions change or agencies are created with applicable missions and responsibilities in this area. For example, the creation of the Environmental Protection Agency (EPA) established a new agency concerned with the electromagnetic environment. The creation of the Occupational Safety and Health Administration (OSHA) in the Department of Labor, with the National Institute of Occupational Safety and Health (NIOSH) for research support, created new agencies with responsibilities for safety and the possible affects of electromagnetic energy on the worker. PL 90–602 gave specific regulatory responsibilities to BRH, affecting HEW's role in this area. The National Environmental Protection Act (NEPA) of 1969 focused additional attention on the potential environmental effects of nonionizing radiation. Additionally, new programs such as the interest of the National Cancer Institute (NCI) in the possible use of radio-frequencies/microwaves in the diagnosis and therapy of cancer, the NASA and ERDA activities associated with a possible solar power satellite system involving the transmission of energy by microwaves, and other energy related uses of the radio spectrum are being taken into account in the review and coordination process.

2. The OTP does not normally deal with state agencies; however, a number of the Federal agencies involved in the cooperative program do. We do maintain awareness of state activities pertaining to nonionizing radiation and provide information or assistance to state agencies as requested.

3. In discussing regulatory programs there are three principal areas of regulatory activity to consider:

Electronic product radiation: the control of emission of radiation from electronic products for the protection of public health and safety.

Occupational safety: the control of working conditions to ensure the protection of the safety and health of workers.

Environmental: the control of radiation to prevent damage to the environment and biosphere or to the health and welfare of man (non-occupational).

Additionally, there are programs concerned with authorizing spectrum use which do not originate, but include and implement, considerations and criteria for biological safety.

Other programs, not directly involving regulation, which contribute include those concerned with developing scientific knowledge; and mission oriented programs, which produce information needed to establish a better understanding of effects and meaningful definitions of safety.

The OTP research coordination activity has been primarily concerned with developing sound scientific knowledge upon which to base assessments of effects and definitions of exposure safety, and has not been directed to the regulatory process per se. However, the existence of this unique multiagency research program has played a considerable part in effecting a continuing dialogue between the regulatory organizations such as EPA, BRH, OSHA, etc.

OTP is concerned that any regulatory controls should be based on dependable scientific data and that there should be a consistent basis and logical rationale for standards in the aforementioned areas. Attention should also be given to risk, benefit considerations and cost/benefit where applicable (i.e. device emission standards).

Current scientific knowledge of electromagnetic radiation effects on man is not adequate to permit assessment of all possible risks, particularly for relatively low-level and long-term exposures. Known harmful effects can be caused by excessive heating, but concrete scientific evidence that harmful effects can be caused by other mechanisms of EMR interaction with biological systems is lacking.

The American National Standards Institute (ANSI) recommended a nonionizing radiation protection standard of 10 mW/cm^2 from 10 MHz to 100 GHz "to prevent possible harmful effects on mankind," based primarily upon thermal considerations. OSHA adopted this ANSI standard making it applicable to those exposed in the course of their employment (in 29 CFR 1910.17). It also applies to government employees through Executive Orders 11612 and 11807 which directed all Federal agencies to be consistent with all OSHA standards. The ANSI recommendation has not been applied to the general public by Federal action, although in practice it is widely used.

With regard to environmental standards for the general public (non-occupational), standard authorities are somewhat unclear. The establishment of EPA included the transfer of the authority of the former Federal Radiation Council, which did not specifically refer to nonionizing radiation. The EPA interprets this authority to include nonionizing radiation. There are other areas where regulatory and jurisdictional authorities are not entirely clear. Again, however, OTP's principal concern for any standard is that there be a rational basis for its issuance.

A different philosophy applies to the class of standards designed to control product emissions such as those pertaining to microwave ovens. They are intended to minimize all unnecessary radiation associated with a product, insofar as practicable, and are only indirectly related to human safety standards. It is interesting that, in terms of actual radiation in the environment, the oven standard is effectively more stringent than the guidelines recommended by ANSI, but this is due to the rationale for equipment emission standards. The failure to distinguish between emission and exposure can cause a misunderstanding of what is "safe" and a misunderstanding of the basis for a particular standard decision.

With regard to funding, the necessity for continuing research to develop an adequate basis for regulatory determinations must be underscored. This research requires expenditures greater than are presently being budgeted by the active research participants in the Federal program,. The program was structured to take advantage of existing responsibilities and capabilities. Agency mission and operational needs were viewed as incentives to utilize their technical capabilities to conduct research. However, nonionizing radiation must compete within each agency for priority and funding against many other research requirements, some with legimately higher mission or public interest importance.

While considerable research progress has been made, there remain many unanswered questions to date. However there are emerging clearer directions of research needs, many of which are very costly and would require a total or near-total investment of the currently budgeted resources of any single agency. Examples of these needs include studies involving long-term, chronic exposures, additional studies of basic mechanisms of interaction, studies of exposed people, and further development and refinement of dosimetry. A mechanism should be established to supplement the normal agency budgetary process in the ERM area to permit such work to be undertaken which would make effective use of the capabilities developed by the agencies involved. A rough estimate of required funding would be two to three times the present level of expenditure.

4. Any proposal to consolidate all Federal radiation activities into a single agency should give careful consideration to the tradeoffs involved.

It is important to ensure that reorganization along subject versus functional lines does not simply create additional bureaucracy, redundancy, and need for coordination with existing mission responsibilities of established agencies. The "consolidation of all radiation activities" implies that a single agency would be responsible for all aspects of radiation including all regulation (e.g. safety, environmental standards, devices, and radiation use), compliance, and enforcement, as well as research pertaining to safety and the development of new applications for use. Clearly this would overlap the established mission responsibilities of a number of agencies and require extensive reorganization to modify their missions to make exception for this one area. For example: Would DOL/

OSHA maintain its regulatory responsibility for occupational safety in all areas except radiation? Would an "Energy Agency" have responsibility for development, new technology and safety research, (and perhaps regulation) for all forms of energy except those involving ionizing or nonionizing radiation?

There is also the question of the desirability of having a single agency responsible for all radiation activities—research, use, and regulation. The former AEC had such a consolidated role for ionizing radiation and serious questions were raised as to whether this was desirable, based on the inherent conflicts between these functions. This resulted in reorganization in which the functions were dis-associated.

Other considerations include:

It is difficult to carry out sustained basic research in an agency which has regulatory responsibilities because the exigencies and demands of regulatory activities predominate. The requirement to develop standards and compliance and enforcement programs place heavy demands on limited resources—people facilities and budgets—often at the expense of biomedical research. Research tends to be constrained to the minimum necessary to support a standard and to be shifted from area to area (e.g., ionizing, light, microwave) as dictated by the business of standard setting. Generally, this places emphasis in areas with recognized problems and not on fundamental research needed to anticipate or determine whether a problem might exist.

The priorities established for research may not be responsive to the needs of other departments or agencies. For example, a unique, and mission critical, radiating system under development by one agency might be delayed pending research or authorization by the "consolidated" agency.

Research conducted only under the auspices of a single agency can lead to lack of flexibility in funding new approaches and possible loss of necessary research replication which can impair scientific credibility.

Consolidation or reorganization of research institutions can cause disruption, even a severe setback, to established research efforts. This was the case during the creation of the Environmental Protection Agency research program from within the resources of the Bureau of Radiological Health.

Consolidation could have some benefits such as better delineation of regulatory responsibilities and elimination of overlapping research requirements. However in view of the myriad of uses for radiation over the entire spectrum, it is unlikely that a consolidated agency could, in practice, eliminate all overlap or that it would be prudent to do so.

Department of Transportation,
Federal Aviation Administration,
Washington, D.C., June 1, 1977.

Hon. Wendell H. Ford
Chairman, Subcommittee on the Consumer, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

Dear Mr. Chairman: This is in further response to your letter of May 20 requesting information on Federal radiation, research, and regulatory programs.

At the outset, I should point out that the Federal Aviation Administration (FAA) has no regulatory powers with regard to either ionizing or nonionizing radiation. However, as one of the Federal Government's largest users of microwave producing equipment, we do have a considerable interest in radiation protection, both from the microwaves produced and the ionizing radiation associated with the production of such microwaves. We are also concerned with ionizing radiation from cosmic sources and nuclear testing and their effect upon the passengers of high altitude aircraft, such as the supersonic transport, and the ionizing radiation produced by isotopes which are transported in both commercial passenger and cargo aircraft.

In April 1967, the FAA formed an Advisory Committee on Radiation Biology Aspects of Supersonic Transport. This Committee consisted of 10 scientists who conducted studies on the biological aspects of cosmic radiation at altitudes to be flown by the SST. During its 8-year period of existence, the Committee met approximately 3 times annually and the results of their findings were reported to the Federal Air Surgeon at various intervals. The amount of money expended on this study was approximately $40,000 and the final report on SST operations was published in the September 1975 issue of Aviation Space and Environmental

Medicine. The Committee also drafted a report concerning cosmic radiation in subsonic flights at conventional altitudes which will be published before the end of 1977.

With the proposed construction of the American supersonic transport in 1968, we initiated a program at our Civil Aeromedical Institute in Oklahoma City, Oklahoma, to investigate the effects of cosmic and other types of ionizing radiation and their biological effects on passengers and crewmembers. Between the years 1968 and 1977, we expended a total of $855,000 in research funds and a total of 31 man years on such ionizing radiation studies. These studies consisted of exposing animals to various dosage rates of ionizing radiation and extrapolating the results to arrive at the possible biological effects upon human beings. As previously stated, these studies were carried on with relation to the possible biological effects of cosmic radiation on aircraft passengers aboard supersonic aircraft and similarly to determine the effects on passengers and crewmembers aboard subsonic aircraft transporting radioactive isotopes.

Since nuclear weapons test debris can result in possible contamination of civil aircraft, the FAA coordinates with other Federal agencies during such testing situations. In this regard, the Energy Research and Development Administration, pursuant to interagency agreement, is adapting their models to produce operational short-range and long-range forecasts of radioactive clouds in a format prescribed for FAA use in protecting the health and welfare of aircraft passengers and crews when nuclear weapons tests are conducted.

The FAA has 109 long-range radars, 159 short-range radars, and 930 VORTACs. All of these pieces of equipment, besides producing microwave, also produce ionizing radiation. Whenever more than 10,000 kilovolts are introduced into certain power tubes, x-radiation or ionizing radiation is an unwanted by-product which may affect the personnel operating such equipment. The FAA insists that all electron tubes producing such radiation be completely shielded and clearly marked in accordance with applicable safety regulations. The FAA also maintains a nucleus or industrial hygienists who monitor these locations with radiation detecting equipment to ensure that all safety regulations are met and that FAA personnel are properly safeguarded.

With regard to the microwave radiation produced by the previously mentioned equipment, the FAA insists that safety precautions are met. In the construction and installation of all microwave producing equipment, site selection is given the utmost consideration, particularly in the case of radars. Long-range radars which produce significant amounts of microwave radiation are mounted on 75-foot towers and primarily sited in remote areas. Careful consideration is given to siting to prevent human hazard, mechanical hazard, and possible pacemaker interference. In all cases, the protection of the public from exposure to such radiation is our primary consideration. Constant checks are made by FAA industrial hygienists to assure that operating personnel are completely protected from the hazards of microwave radiation.

To date, research into the effects of microwave radiation has been confined to a study of the microwave radiation produced by all types of FAA navigational facilities. This study was performed for the FAA by the National Bureau of Standards under a $250,000 contract extending over the years 1973, 1974, and 1975. This particular study was authorized by Secretary Volpe at the request of the Office of Telecommunication Policy. The purpose of this study was to determine the actual amounts of microwave radiation produced by all of the various FAA navigational equipment and to give the FAA an indication of what, if any, hazards existed and what remedial action might be needed. We have also instituted a study to determine the effects of microwave radiation on human health. This study is to begin in fiscal year 1978 and is presently funded at $24,500. We have already started to interview other Federal agencies with regard to their human effects research and we are considering studying the effect of chromosome changes in irradiated tissue as it is a known fact that where cancer is involved, chromosomal changes are always noted.

As previously noted, the FAA is concerned with the carriage aboard aircraft of radioactive materials, and prior to the enactment of the Transportation Safety Act of 1974 (Public Law 93–633), the FAA was responsible for prescribing regulations governing the air transportation of hazardous materials. Pursuant to this Act, the Department of Transportation's Materials Transportation Bureau (MTB) assumed authority on July 7, 1975, for promulgating regulations governing the carriage of hazardous materials by all modes of transportation.

The FAA's present responsibilities in this area now consist of coordination with MTB on regulatory matters and surveillance and enforcement activities.

A summation of the in-house positions, extra-mural funds, and total funds for FAA activities is contained in the enclosed matrices. We note that the funds listed on the enclosed charts represent our best estimates of total costs but may not be precise due to the limited time available to compile these data. Also, the figures shown for transportation of hazardous materials reflect all forms of hazardous materials and are not available respecting radioactive materials alone.

With respect to the questions posed in your letter, we offer the following comments:

1. The passage of the Occupational Safety and Health Act of 1970 has had a profound effect upon our agency's responsibilities with regard to radiation hazards. The rules regarding the protection of agency employees are requiring the annual inspection of those facilities which produce either ionizing radiation or microwave radiation, or both. This has placed an unusual workload upon our industrial hygienists and may require additional personnel in order that we may conduct the inspections necessary to comply with the Act.

Additionally, as noted in the body of our letter, subsequent to the enactment of the Transportation Safety Act of 1974, our regulatory authority for air transportation of hazardous materials (including radioactive materials) was assumed by the Materials Transportation Bureau. The FAA still retains surveillance and enforcement responsibilities. We understand that MTB is also providing information to the Committee which will expand on their specific responsibilities.

2. We are not required to contact or coordinate with State agencies and we have never discerned any confusion as to respective responsibilities.

3. We believe that the present regulation of radiation programs could be improved by assuring that all agencies involved in radiation programs are using the same methods to arrive at final determinations. Specifically, we believe that the methods of measuring the amounts of radiation produced in both the ionizing and non-ionizing spectrum should be clearly defined. In other words, the method of measuring, and the equipment used, should be standardized to assure that results obtained by different agencies are consistent. We do not have adequate information to satisfactorily address the issue of present funding levels in the areas of research and instrumentation on a government-wide basis.

4. While the consolidation of radiation activities into one Federal agency would certainly make coordination on radiation matters much simpler, we are not prepared at this time to advocate the institution of such an agency. We believe there are a number of variables which need to be carefully examined; for example, the extent to which various agencies can presently apply their specific areas of expertise to radiation-related matters affecting their agency programs should be considered.

Thank you for providing the FAA the opportunity to offer our views on these matters. We will be pleased to work with your Subcommittee's staff if additional information is needed.

Sincerely,

BRUCE SELFON.

Enclosure.

Department of Transportation,
Materials Transportation Bureau,
Washington, D.C., June 22, 1977.

Hon. Adlai E. Stevenson,
Chairman, Subcommittee on Science, Technology, and Space, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

Dear Senator Stevenson: Thank you for your and Senator Wendell H. Ford's letter of May 20, 1977. The matrix form for ionizing radiation has been completed as it pertains to the programs of the Materials Transportation Bureau relative to ionizing radiation. There are no relevant programs in the nonionizing radiation area.

With regard to the specific questions in your letter, we offer the following:

1. The major change in Federal jurisdictions between 1968 and 1977 which has affected this Bureau was the formation of the U.S. Nuclear Regulatory Commission (NRC) and the Energy Research and Development Administration (ERDA), as a result of the Energy Reorganization Act of 1974 which disestablished the U.S. Atomic Energy Commission (AEC). Whereas our liaison on matters relating to regulation of the safe transport of radioactive materials was principally with the AEC, it now is with the NRC. The March 22, 1973, Atomic Energy Commission/Department of Transportation (DOT) Memorandum of Understanding (copy enclosed) is currently being updated between DOT and NRC.

2. The contacts between the MTB and state groups pertain solely to matters relating to the regulations for the safe transport of radioactive materials. These contacts involve questions on the interface of Federal versus state regulatory programs for safe transport of hazardous and radioactive materials, enforcement and compliance questions, and training and planning for handling of transportation emergencies. Due to the provisions of Section 112 of Public Law 93–633, the Transportation Safety Act of 1974, contacts with the states are increasing relative to the effect of state regulation on Federal regulations and possible preemption of inconsistent state regulations.

3. The present radiation regulatory programs could be improved by amending the Atomic Energy Act to include the regulation of machine-produced radioactive materials, in addition to the by-product, source, and special nuclear materials now regulated by NRC. We note that in its "agreement state" programs, the NRC requires that the state's jurisdiction include all forms of radioactive materials. Such consistency should be added to the NRC's authority in regulating its "non-agreement" state licensees.

4. The proposals to consolidate all Federal radiation activities into one Federal radiation agency are, in our opinion, oversimplistic. In the area of transportation, if this were done (i.e., selecting one type of hazardous material for separate regulation), a logical follow-on would suggest that separate Federal agencies be established for consolidated Federal regulation of all aspects of explosives, flammables, corrosives, toxic materials, etiologic agents, etc.

It is our feeling, therefore, that consolidation of all Federal regulatory authority into a single agency would be counterproductive to the total regulatory system.

Sincerely,

John Fearnsides
(For Alan A. Butchman, Acting Director).

Enclosures.

Further Descriptions to Table Entries

The programs involving radiation regulations are principally focused on the regulation of the transportation of hazardous materials in interstate and foreign commerce. Radioactive materials are one of the major classes of regulated hazardous materials. Two areas as listed on the matrix for ionizing radiation are:

CRITERIA AND/OR STANDARDS DEVELOPMENT

This effort involves the development and promulgation of amendments to the Department's Hazardous Materials Regulations in 49 CFR, Parts 100–199, as they affect transport of radioactive materials. Close coordination of this effort is maintained with the U.S. Nuclear Regulatory Commission and prior to 1975 with its predecessor agency, the U.S. Atomic Energy Commission. Due to statutory overlap in jurisdiction, each agency operates under a written DOT/AEC Memorandum of Understanding (copy enclosed in letter), which is currently in the process of being updated between DOT and NRC.

STATE/FEDERAL LIAISON

In addition to frequent liaison with the U.S. NRC, liaison is carried out with several other Federal agencies, including ERDA, EPA and HEW (Bureau of Radiological Health) on matters relating to radiation safety in transportation.

With respect to individual states, increasing liaison is carried out on matters relating to regulations enforcement, compliance, and accident reporting for radioactive materials. Additionally, liaison is increasing on matters relating to adoption of regulations by states and the possible impact of Section 112 of the Transportation Safety Act of 1974 (Public Law 93–633), dealing with preemption of Federal regulations.

MEMORANDUM OF UNDERSTANDING BETWEEN THE UNITED STATES DEPARTMENT OF TRANSPORTATION AND THE UNITED STATES ATOMIC ENERGY COMMISSION

For Regulation of Safety in the Transportation of Radioactive Materials Under The Jurisdiction of the Department of Transportation and the Atomic Energy Commission

The Department of Trasportation (DOT, under the Transportation of Explosives Act (18, U.S.C. §§ 831–835), the Dangerous Cargo Act (R.S. 4472, as amended, 46 U.S.C. 170), and Title VI and § 902(h) of the Federal Aviation Act of 1958 (49 U.S.C. 1421–1430 and 1472(h)), is authorized to regulate the transportation of explosives and other dangerous articles, including radioactive materials. The Atomic Energy Commission (AEC), under 42 U.S.C. Chapter 23, is authorized to license and regulate the receipt, possession, use and transfer of "by-product material," "source material," and "special nuclear material." The AEC, through appropriate contractual provisions as implemented by AEC Manual requirements and specific instruction, also controls the receipt, possession, use, and transfer of radioactive material by those AEC contractors who are exempt from AEC licensing requirements.

For the purpose of developing, establishing, and implementing consistent and comprehensive regulations and requirements for the safe transportation of radioactive materials, and avoiding duplication of efforts, DOT and AEC agree, subject to their respective statutory authorities, as follows:

I. DEVELOPMENT OF STANDARDS

A. DOT will develop safety standards governing all radioactive material packings and their contents, and the classification, labeling and marketing of all radioactive material packages, except for those types of radioactive material and areas of technical competence specified in paragraph B.

B. AEC will develop safety standards, for packaging design and performance, for packages of fissile materials and Type B and large quantities of radioactive material in the following areas: (1) Structural materials of fabrication; (2) Closure devices; (3) Structural integrity; (4) Criticality control; (5) Containment of radioactive material; (6) Shielding retention; (7) Generation of internal pressure; (8) Internal contamination; (9) Protection against internal overheating; and (10) Quality control of packaging fabrication and continued use.

C. DOT will deveolp safety standards governing mechanical conditions of carrier equipment and qualifications of carrier personnel, carrier loading, unloading, handling and storage of radioactive material, and any special transport controls to be provided during carriage, including construction standards for transport vehicles.

II. REGULATIONS

A. DOT will adopt regulations imposing, on shippers and carriers subject to its jurisdiction, those standards developed by AEC and DOT pursuant to Section I of this memorandum, and will adopt a requirement for AEC approval of packages for shipment of fissile material, and Type B and large quantities of radioactive material by all persons not otherwise subject to the provisions of 10 CFR Part 71 or AEC Manual requirements, but subject to DOT jurisdiction.

B. AEC will adopt regulations and contractual requirements imposing, on AEC licensees and license-exempt contractors, those standards which it has developed pursuant to Section I, and procedures and criteria for approval of proposed package designs and transport controls peculiar to the package design, and will require that AEC licensees and license-exempt contractors comply with the applicable requirements of DOT regulations when transporting or shipping radioactive material, when those persons are not otherwise subject to the provisions of DOT regulations.

III. PACKAGE REVIEW

A. AEC will evaluate package designs for fissile material and Type B and large quantities of radioactive material, and will, if satisfactory, issue approvals therefore (i.e., an AEC license, and AEC certificate of compliance, or other AEC package approval) directly to the person requesting the evaluation.

B. AEC will evaluate package designs for specification containers and will make appropriate recommendations to the DOT for its consideration.

C. With respect to those designs of packages intended to be used for transporting radioactive material in the United States, which have been approved by foreign competent national authorities but which require revalidation under DOT regulations, DOT will submit to AEC for approval those designs of packages (1) for Type B quantities where, in DOT's opinion, evaluation by AEC is warranted, (2) for fissile material, and (3) for large quantities of radioactive materials.

IV. INSPECTION AND ENFORCEMENT

A. Each agency will conduct an inspection and enforcement program within its jurisdiction, to assure compliance with its requirements.

B. DOT and AEC will consult with each other on the results of their inspections, and each will take enforcement action as it deems appropriate within the limits of its authority.

V. ACCIDENTS AND INCIDENTS

A. DOT will require notification and reporting of accidents, incidents, or suspected leakage involving radioactive material packages if such occurs or is discovered while in transit. When such cases occur during transit, DOT will be the lead agency[1] in investigation of the occurrence and in preparation of the report of the investigation.

B. AEC will require notification and reporting of accidents, incidents, and suspected leakage involving radioactive material packages if such occurs or is discovered prior to delivery of the radioactive material packages to a carrier for transport or after delivery to a receiver. When such cases occur other than during transit, AEC will be the lead agency[1] in investigation of the occurrence and in preparation of the report of the investigation.

C. Notwithstanding paragraphs A & B, this section V. does not affect the authority of the National Transportation Safety Board.

VI. NATIONAL COMPETENT AUTHORITY

A. DOT will be the national competent authority with respect to the administrative requirements set forth in the Regulations for the Safe Transport of Radioactive Materials of the International Atomic Energy Agency. In issuing certificates of national competent authority for the United States under those regulations, DOT will require, for containers other than DOT specification containers, an AEC certificate of approval or a showing that the shipment is within the scope of an exemption or general license under 10 CFR Part 71 or AEC Manual Chapter.

B. DOT will act as the representative of the United States to the International Atomic Energy Agency and other international groups on matters pertaining to transportation of radioactive material. AEC will provide technical support and advice to DOT in this area.

VII. EXCHANGE OF INFORMATION

A. Prior to issuance of any regulations by either DOT or AEC involving transportation of radioactive materials, each agency will advise and consult with the other to avoid possible conflict in the regulations and to assure that: (1) the regulations are in the public interest; (2) the regulations are in accord with the best-known, practicable means of providing safety in transportation; (3) the effect of these regulations will not be inimical to the common defense and security of the United States; and (4) the regulations will not constitute an unreasonable risk to the health and safety of the public.

B. DOT and AEC will exchange information, consult with, and assist each other within the areas of their special competence in the development and enforcement of regulations and requirements. Each agency will make available to the other, subject to security requirements and statutory provisions affecting the release of information, summaries of inspection records, investigations of serious accidents and other matters relating to safety in the transportation of radioactive materials.

---

[1] The lead agency has primary responsibility for investigating the occurrence and preparing the report of the investigation. The other agency may participate in the investigation with the lead agency or conduct a separate investigation if it chooses to do so.

VIII. WORKING ARRANGEMENTS

A. AEC and DOT will designate appropriate staff representatives and will establish joint working arrangements from time to time for the purpose of administering this Memorandum of Understanding.

IX. GENERAL

A. Nothing herein is intended to affect the statutory exemption of shipments of radioactive materials made by or under the direction or supervision of the AEC or Department of Defense in accordance with the provisions of 18 U.S.C. § 832(c).

B. This agreement shall take effect upon the signing by authorized representatives of the respective agencies, and shall supersede in its entirety the March 21, 1966, Memorandum of Understanding between the ICC and AEC.

C. Nothing in this Memorandum is intended to restrict the statutory authority of either agency.

Done at Washington, D.C., in triplicate, this — day of March 1973.

For the U.S. Department of Transportation:

CLAUDE S. BRINEGAR,
Secretary,

For the U.S. Atomic Energy Commission:

DIXY LEE RAY,
Chairman.

DEPARTMENT OF TRANSPORTATION,
U.S. COAST GUARD,
Washington, D.C., July 18, 1977.

Hon. WENDELL H. FORD,
Chairman, Consumer Subcommittee, Committee on Commerce, Scicnce, and Transportation, U.S. Senate, Washington, D.C.

DEAR SENATOR FORD: This is in response to your letter of May 20, 1977, regarding federal responsibilities in the areas of radiation health and safety research and regulation. The completed matrices concerning involvement in radiation regulatory and research programs for ionizing and nonionizing radiation are forwarded as enclosures (1) and (2) respectively. With regard to the four specific questions posed in your letter the following responses are offered:

1. In 1975 a new Bureau, the Materials Transportation Bureau, was formed within the Department of Transportation. This Bureau was delegated the regulatory authority, formerly vested in the modal administrations, regarding the transport of packaged hazardous materials, including radioactive materials. This action consolidated the packaged hazardous materials regulatory authority in a single agency. The result of centralizing this authority in one Bureau has the effect of decentralizing the authority of the modal administrations to regulate all aspects of transport in their particular mode. Therefore, as a result of the establishment of the Materials Transportation Bureau in 1975, the Coast Guard is no longer responsible for issuance of regulations governing the transport of radioactive materials by vessel. However, responsibility for enforcement of these regulations remains with the Coast Guard.

2. Since the Coast Guard is now only responsible for the enforcement of federal regulations governing the transportation of radioactive materials by vessel, there is little need for coordination and contact with state agencies. There has been no confusion concerning the respective responsibilities of the Coast Guard and state agencies in this area.

3. The Coast Guard's involvement in the regulation of radioactive materials is rather limited. I am, therefore, unable to offer suggestions regarding improvement of the overall system of regulations of these materials. Funding for the Coast Guard's role of enforcement of the regulations governing transportation of radioactive materials by vessel is considered adequate.

4. I believe that great care should be taken in, and careful consideration given to, consolidating all federal radiation activities into one federal radiation agency. In general, the task of setting basic standards for radiation regulation can be assigned to a single agency. However, implementing regulations requiring specialized expertise in other areas should rest within those agencies having that expertise. For example, in the transportation of radioactive material by vessel, while it is logical that the basic standards should be set by the agency with the greatest technical expertise, the implementation of these standards should be carried out by the Coast Guard, the agency having the expertise in the overall area of marine safety.

If I can be of further assistance, please do not hesitate to contact me.

Sincerely,

O. W. SILER,
Admiral, U.S. Coast Guard, Commandant.

ENCLOSURE (2)

VETERANS ADMINISTRATION,
Washington, D.C., July 1, 1977.

Hon. WARREN G. MAGNUSON,
Chairman, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: I am pleased to respond to your letter of June 9 in regard to the comprehensive hearings of the Senate Committee on Commerce, Science, and Transportation concerning review and evaluation of federal radiation research and regulatory programs.

With respect to the questions posed in your letter, we offer these comments:

1. Reorganization Plan No. 3 of 1970, creating the Environmental Protection Agency, has led to close cooperation between the Veterans Administration, and this new agency. For example, three members of the Veterans Administration Central Office participated in the activities of the Environmental Protection Agency Subcommittee which produced the background report, "Recommendations on Guidance for Diagnostic X-Ray Studies in Federal Health Care Facilities."

The Occupational Safety & Health Act of 1970 has resulted in the proliferation of reporting requirements.

Public Law 93–438, the Energy Reorganization Act of 1974 transferred our licensing for the use of spontaneously ionizing material, and site inspections pertaining to their use, from the Atomic Energy Commission to the Nuclear Regulatory Commission on January 19, 1975. The close, cordial, cooperative liaison that the Veterans Administration enjoyed with the now defunct Atomic Energy Commission, has continued and been expanded.

Public Law 93–633, Transportation Safety Act of 1974, making the Federal Aviation Administration responsible for prescribing regulations governing air transportation of hazardous materials, resulted initially in concern that delivery of the radionuclides used in medicine might be impeded. However, interpretation of the law has dispelled this concern.

The changes in jurisdiction described have multiplied our reporting activities.

2. We are not required to contact or coordinate with state agencies, and we have not perceived any confusion as to respective responsibilities of state and federal agencies.

3. We believe that the present regulation of radiation programs could be improved by requiring that all agencies involved in radiation programs use the same standards for measuring both ionizing and nonionizing radiation, and for calibration of equipment. These standards should be clearly defined. We do not have the data necessary to give an informed response on the subject of the adequacy of current government-wide funding levels in radiation regulation.

4. Our reaction to proposals to consolidate all federal radiation activities into one federal radiation agency is that, although there are attractive features to the single agency concept, so many diverse considerations are involved in this matter, that careful in-depth examinations into the subject should be made before any decision is reached.

We have condensed your matrix, using only those columns which apply to Veterans Administration activities. There is no information to report prior to 1972.

We do not have the data to furnish a description of each project and its cost. Our listing of positions, and funds expended, incorporate programs in all the categories listed in the heading of the matrix summary enclosure.

Thank you for providing the Veterans Administration the opportunity to offer our views on these matters. We shall be pleased to work with the Staff of your Committee if additional information is needed.

Sincerely,

RUFUS H. WILSON,
Deputy Administrator,
(For Max Cleland, Administrator).

Enclosure.

U.S. Department of Commerce,
National Bureau of Standards,
Washington, D.C., June 7, 1977.

Senator Adlai E. Stevenson,
Chairman, Science, Technology, and Space Subcommittee, Committee on Commerce, Science, and Transportation U.S. Senate, Washington, D.C.

Dear Senator Stevenson: This is in response to your letter, co-signed with Senator Wendell H. Ford, dated May 20, 1977, which requested information about projects or programs relevant to radiation health and safety research and regulation. This same letter is also being sent to Senator Ford.

The comprehensive listing and short description of appropriate NBS activities is attached, utilizing the format of the suggested matrices. Although the brief categorizations of studies as indicated by the column headings may have been misinterpreted by us, that should become evident from the accompany descriptions and enable necessary adjustments.

Your letter requested written response to four specific questions. Our reply to each question follows.

(1) The significant changes in jurisdiction since 1968 were the Radiation Control for Health and Safety Act (1968), Reorganization Plan #3 (1970), and the Occupational Safety and Health Act (1970). Although its impact on NBS is not yet clear, the Medical Devices Amendment to the Food, Drug, and Cosmetic Act (1976) is expected to be significant in that regard. The effect of these changes in jurisdiction has been largely due to the inception of new regulations, rather than the result of transfers of regulatory authority.

By its organic legislation, NBS responsibilities include the development and maintenance of the physical standards of measurement and the provision of means throughout the country for their effective use. NBS is also charged with the responsibility of providing assistance to other agencies in their needs for measurements, standards, and essential technical data. Because enforcement of regulations is frequently based on measurements, the effect on NBS has been substantial. Expanded activities become necessary to provide the measurement standards, instruments, and measurement quality assurance needed to support new regulations. These services from NBS are needed both by the regulators and by those who are regulated.

Thus, the promulgation of new regulations to protect the public safety in ionizing radiation and in diverse areas of non-ionizing radiations such as ultrasonic radiation, rf and microwave radiation, ultraviolet radiation, and laser radiation have required new efforts by NBS to ensure that adequate measurement standards, and measurement techniques are developed.

In addition to measurement and standards needs to directly support present regulatory actions, improvement in technology or potential new hazards to public safety have required NBS actions. For example, it is now widely accepted that effective cancer radiation therapy requires radiation dosimetry measurements which are accurate to 5 percent or better, yet many treatment centers do not routinely achieve such accuracy. Through measurement assurance testing programs, NBS is attempting to improve this situation. Similarly, the possibility that atmospheric modification by freons and other man-made substances will result in change in the UV transmission of the atmosphere has stimulated NBS efforts to develop improved UV measurement techniques and standards required for accurate long-term monitoring of these possible effects.

These many new needs for NBS services have seriously strained our ability to respond in a proper and timely manner.

(2) During the past few years, contacts between NBS and state radiation control programs has increased substantially. Beginning in 1975, NBS surveyed measurement needs and capabilities in state ionizing radiation programs. The Conference of Radiation Control Program Directors created a special task force to cooperate with NBS during and after the survey. At this time, several pilot programs are being initiated to provide needed services to state programs, thereby assuring that measurements made in those programs will be sufficently accurate and reliable. This is particularly important since the ultimate responsibility for protection of the public from radiation hazards rests in the state programs.

The National Bureau of Standards is required to provide services to state governments, but is not specifically required to contact or coordinate with state agencies. However, to use limited resources effectively and efficiently coordination and contact such as that described above is generally advisable. This is consistent with the President's recently expressed desire to involve state officials in the development of federal programs which have state impact.

There is some confusion about respective responsibilities of state and federal regulatory agencies. The variety of possible agreements, contracts, and preemptions adds to this confusion. In addition, many regulations at the federal and state levels have boundaries or limitations which are not immediately obvious. Some apply only to manufacture and distribution of a product or device; others also include control over use. In some cases, state regulations are applicable in general areas where no federal regulations exist. The confusion is compounded because of the several federal agencies involved and the sometimes apparent duplication of jurisdiction and inadequate coordination between federal agencies.

(3) At present, federal regulatory authority allows adequate provision for control of the manufacturers of radiation producing devices and for the protection of radiation workers who might be exposed to radiations from these devices. However, federal authority to regulate how these devices are used is unclear. This is particularly true in the healing arts. Thus, for example, although it is clearly a medical decision as to how much radiation dose a patient should receive in a cancer therapy treatment, the question of whether the prescribed dose was actually delivered is not a medical decision. Considerable evidence exists from measurement assurance testing done by NBS and by others that the prescribed dose is often not delivered with adequate accuracy. Federal regulatory authority to require adequate measurement quality assurance is unclear.

Similarly, no clear federal regulatory authority exists regarding naturally occurring radioactive substances.

For practical reasons, the state radiation control programs have responsibility for enforcing most of the regulations promulgated by both federal and state agencies. In spite of this major responsibility for public safety and health, state programs are generally understaffed, underpaid, lack adequate equipment, and often have inadequately trained staff. In many instances, the diversity of federal regulations and regulatory agencies compounds the problems. Measures should be taken to provide more support to state programs and to eliminate practices that hamper their efficiency.

From the NBS viewpoint, the deficiencies which deserve priority attention in present regulations are the lack of explicit requirements for measurement accuracy. Although enforcement of most regulations depends on measurements which are defendable in court, very few measurements would pass that test. The primary reason is the lack of assured high quality in regulatory measurements. Such quality could be achieved through measurement assurance programs which would require periodic calibrations of instruments and tests of performance. Prescribed methods could be required to achieve meaningful traceability to national measurement standards maintained by NBS. Closer cooperation between NBS and the regulatory agencies is necessary to achieve this goal. Such actions are being initiated by NBS.

As mentioned above, funding of state radiation control programs is generally inadequate. This is also true of federal agencies. For NBS, resources at present are inadequate to develop all of the needed measurement standards in both ionizing and non-ionizing radiation on a proper time scale to support regulatory needs, or to provide adequately the measurement assistance needed by state regulators, by industry, and by researchers involved in developing the data base for radiation regulations.

(4) At its 5th annual meeting in May 1973, the Conference of Radiation Control Program Directors passed a resolution to "urge the Congress of the United States to consider this serious problem of fragmentation and take the necessary legislative action to consolidate the various federal responsibilities relating to radiation protection of the public and worker within one agency." The reasons for the resolution were stated as "duplication, inefficiency, contradictions, and complexities in communication." These continue to be valid reasons why consolidation of federal regulatory activities might be desirable.

The responsibilities of NBS in providing measurement support for regulatory programs could be fulfilled more efficiently and effectively if interactions were required with only one federal regulatory agency. At this time, appreciable effort is expended in coordination of activities with the various agencies, and serving as a communications link or referee among them.

Despite these advantages of a single federal agency responsible for radiation regulation, we believe any such consolidation into a single agency should be taken very cautiously. Some obvious areas of overlapping responsibilities among agencies should be corrected, and some degree of consolidation would be desirable. However, one single agency responsible for federal regulation of ionizing and non-ionizing radiation, radiation safety in nuclear power development, radiation safety in medical practice, environmental radiation both ionizing and non-ionizing, etc., could become very large and difficult to manage, could have substantial internal conflicts of interest, and would find it difficult to achieve adequate communications with the communities they must regulate. Better results might be achieved by taking steps to ensure that adequate communications, cooperation and planning exists between existing federal regulatory agencies.

I hope this response will be useful in the forthcoming deliberations of the Senate Committee on Commerce, Science, and Transportation. If there is any additional information that I, or members of my staff, can provide, please feel free to call upon us. Thank you for the opportunity to comment on this important subject.

Sincerely,

ERNEST AMBLER,
Acting Director.

Enclosures.

DESCRIPTION OF NBS PROGRAM

IONIZING RADIATION

NOTE. (1) Funds in thousands of dollars. (2) Extra-mural funds are those obtained from other agencies to support NBS in-house programs. (3) Total funds include support from other agencies and support from the NBS appropriation.

Criteria and/or standards development

Although NBS is a non-regulatory agency it provides input to criteria and standards, particularly with respect to measurement and instrumentation aspects. In addition, significant effort is devoted to providing input to the development of voluntary standards which may themselves be adopted and enforced by regulatory agencies at various levels, or may influence future legislation. Two examples follow.

The goal of one activity is to improve the reliability of the performance of the suppliers of personnel monitoring services in the United States. In cooperation with the BRH and NRC, criteria are being developed for testing the performance of the suppliers on a continuing basis. Due largely to NBS efforts, the pertinent regulatory agencies will be able to require compulsory testing of suppliers of personnel dosimetry services by the year 1979 or earlier. On November 30 and December 1, 1976, joint public hearings were held by the BRH, NRC, and ERDA regarding proposed rulemaking in this field. NBS is also providing leadership of an ad hoc interagency policy committee whose purpose is to ensure that actions of relevant federal and state regulatory bodies are adequately coordinated in this effort.

American National Standards Committee N43 is concerned with standards for equipment used in non-medical radiation applications. NBS serves as the secretariat and provides the chairman of this committee. BRH and the NRC are heavily represented on the N43 subcommittees which produce the voluntary standards published as NBS Handbooks. If an effective voluntary standard exists, regulations may be unnecessary or may refer to the voluntary standard. BRH is particularly interested in a forthcoming N43 standard on industrial x-ray equipment, and will cooperate in the production of a standard for electron microscopes.

State/Federal liaison

The Conference of Radiation Control Program Directors consists of a representative from each state and territorial radiation control program. It began with a meeting which was called to discuss federal-state implementation of the Radiation Control for Health and Safety Act of 1968. The CRCPD is now jointly sponsored by the BRH, NRC, EPA, and NBS. The annual meeting of the group is called the National Conference on Radiation Control. NBS radiation measurement assurance programs were described in a paper presented by an NBS staff member at the 1976 annual meeting.

NBS has initiated a program to assist the states in improving the quality of measurements made for enforcement of regulations which provide radiation safety for the public. Through contracts and agreements, the states have ultimate responsibility for enforcing federal regulations in addition to state regulations. Some of the work of the NBS program wil be accomplished through task forces created by the Conference of Radiation Control Program Directors. These task forces consist of representatives from the states and interested federal agencies.

Monitoring and/or surveillance

This effort is directed toward providing the national reference for measurements made to detect radioactivity in the environment. Included are radioactive contamination from nuclear explosions resulting in fallout, and effluents from power reactors. NBS produces and distributes well-characterized sources of radioactive materials which are used to calibrate measurement systems used in the field. In addition, NBS cooperates with other agencies in providing services necessary to improve the quality of field measurements. Since 1971, a program sponsored by the Nuclear Regulatory Commission has had the general purpose of improving the accuracy and reliability of measurements of environmental radioactivity and reactor effluents. Traceability to NBS is achieved by testing of the

NRC Reference Laboratory and by provision of standard samples and test samples of radioactivity for use in the states and the nuclear power industry.

A similar program was started under sponsorship of the Environmental Protection Agency. Its purpose is to have NBS develop standard reference materials for radiological pollutants associated with energy sources and production, and to conduct traceability studies with the EPA Reference Laboratory.

Medical diagnostic, therapeutic

For almost 50 years, NBS has developed and maintained the primary physical measurement standards which serve as a common reference for measurements made during medical applications of ionizing radiation. These standards are disseminated through calibrations of secondary standards and through measurement assurance programs. Examples follow:

One project carried out in cooperation with BRH provides measurement assurance for cancer therapy with cobalt-60 radiation. Thermoluminescence dosimeters are mailed to users of teletherapy equipment, who irradiate them under prescribed conditions and return them to NBS for evaluation. NRC has responsibility for licensing the safe use of such radiation sources. To date , over one-half of the 1,000 units in the United States have been surveyed. As many of the remaining units as possible will be surveyed this year. It is planned to follow with a similar measurement-assurance survey of linear accelerator sources used for photon therapy, with continuing support from BRH.

A similar NBS service carried out for several years provides a common basis for all electron-beam cancer therapy in the U.S. by establishing traceability to national dosimetry standards. The objective of a related activity is to develop methods, techniques, and apparatus to reduce the radiation exposure to the general population from diagnostic x-ray examinations.

Other biological or physical effects studies

NBS maintains a small but effective program which is directed generally toward development of the basic data which describe the physical interaction of ionizing radiation with biological materials. This program does not attempt to study biological effects of radiation, but forms the measurement basis for effects studies done by others. Accurate, reliable data are essential for understanding the mechanisms by which radiation energy is absorbed in biological or equivalent materials.

Other studies

To disseminate the national measurement standards, NBS calibrates customers' instruments using the national standards as a reference. In addition, special tests are performed on measurement instruments provided by various sponsors. Radioactive sources are also calibrated for appropriate customers. These services are provided on a reimbursable cost basis.

DESCRIPTION OF NBS PROGRAM

LASER RADIATION

NOTE. (1) Funds in thousands of dollars. (2) Extra-mural funds are those obtained from other agencies to support NBS in-house programs. (3) Total funds include support from other agencies and support from the NBS appropriation.

The principal objectives of the program are to (1) develop laser power and energy physical measurement standards for key lasers impacted by the FDA laser performance standard, and (2) develop transfer standards, measurement methods, and a quality control program for laser power and energy measurements so that laser manufacturers can make valid measurements to help them comply with the FDA standard.

A laser power and energy measurement assurance program was established recently by NBS. In this program a calibrated transfer standard is sent to the participant so that he can perform intercomparisons at his site. The measurement analysis is provided by NBS. This measurement assurance program was established in cooperation with the Bureau of Radiological Health.

DESCRIPTION OF NBS PROGRAM

RF AND MICROWAVE RADIATION

NOTE. (1) Funds in thousands of dollars. (2) Extra-mural funds are those obtained from other agencies to support NBS in-house programs. (3) Total funds include support from other agencies and support from the NBS appropriation.

The entry in the column headed "Collection and/or analysis of environmental data" relates to measurements of RF and microwave radiation from communication systems, radars, and navigation systems at airports and on aircraft. This work is supported by the FAA and results are reported to that agency. Instrumentation for the surveys was developed by NBS.

The entry in the "Other Studies" column relates to efforts in measurement theory, techniques, and instrumentation which support measurements made for various purposes. For the most part, these efforts develop the measurement basis required to determine radiation hazards as defined by some other agency or organization. There has been fluctuating support for this program from other agencies, including BRH, EPA, OSHA/NIOSH, and the FAA. A project was recently initiated to develop measurement support for the study of various problems caused by electromagnetic interference.

DESCRIPTION OF NBS PROGRAM

ULTRASONIC RADIATION

NOTE. (1) Funds in thousands of dollars. (2) Extra-mural funds are those obtained from other agencies to support NBS in-house programs. (3) Total funds include support from other agencies and support from the NBS appropriation.

The attached column entry refers to NBS activities leading to physical measurement standards for characterizing ultrasonic transducers and to transfer standards for calibrating radiated ultrasonic power. Two calorimeters for the measurement of time-averaged total power output of ultrasonic transducers have been developed; one resides at BRH to provide them with a basic standard for regulatory action. (BRH provided the indicated other-agency support in 1974 and 1975.) Transfer ultrasonic transducers have been developed for use in evaluating radiated ultrasonic power measuring systems. An international intercomparison of power measurement is being based on this transfer mechanism. A scanning technique for determining field point intensity of radiated ultrasound is well along and will be used to provide a measurement service for the evaluation of medical transducers. It is believed that the point parameters are critical with respect to possible biological damage.

DESCRIPTION OF NBS PROGRAM

ULTRAVIOLET RADIATION

NOTE. (1) Funds in thousands of dollars. (2) Extra-mural funds are those obtained from other agencies to support NBS in-house programs. (3) Total funds include support from other agencies and support from the NBS appropriation.

The NBS program has as its purpose the development of standards and measurement capabilities for UV radiation adequate to satisfy the requirements of modern technology and to provide a national measurement base necessary both for the development of laws and regulations and for ensuring their compliance in order to protect the public and the environment from possible adverse effects of such radiation. A large fraction of the recent work in this area is related to the development of measurement methods for studying the biological and climatological effects of changes in UV radiation reaching the earth from the sun and to the prevention of hazardous public exposure to UV in situations involving industrial UV processing, artificial illumination, and medical therapy.

[1] Identify type of nonionizing radiation, e.g., microwave, ultrasound, etc.

NATIONAL AERONAUTICS AND SPACE ADMINISTRATION,
Washington, D.C., June 9, 1977.

Hon. ADLAI E. STEVENSON,
Chairman, Science, Technology, and Space Subcommittee; Committee on Commerce, Science, and Transportation.

Hon. WENDELL H. FORD,
Chairman, Consumer Subcommittee, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMEN: This is in further response to your letter of May 19, 1977, concerning the Committee's plans to hold hearings to review and evaluate Federal radiation research and regulatory programs.

Enclosed herewith is a report, with attachments, describing NASA's research activities in the radiation field. The format of this response, in lieu of using the matrices provided, has been discussed with Mr. Dan Jaffe of the Committee staff.

Should additional information or clarification be required, NASA will be pleased to work with the Committee staff.

Sincerely,

A. M. LOVELACE,
Acting Administrator.

Enclosure.

RADIATION RESEARCH ACTIVITIES OF THE NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

The NASA Life Sciences division directs a segment of its total research program to studies to determine human health effects of space radiation. These studies are organized under a single Research and Technology Operating Plan (RTOP) which is titled, "Radiation Effects and Protection." The goals of this research are outlined in Attachment 1, but it should be recognized that much of this information is reliant on the research of other agencies.

The NASA program has been considerably reduced over the years to its current $500–600K per year level. Consequently, NASA has narrowed its sponsorship of research projects to those areas which are unique to NASA interests and are not adequately covered elsewhere, either because of the problems themselves, particular aspects of the problems, or timing. NASA current research is, therefore, almost entirely limited to effects (A) and dosimetry (B) of high energy heavy particle (HZE) radiation (cosmic radiation from galactic and solar sources in space), and a smaller effort to extract further information on other forms of ionizing radiation from existing NASA flight and ground-based data sources. The HZE research is heavily dependent upon support of the Bevalac by the Energy Research and Development Administration. The Bevalac, a facility of the Donner Laboratory at the University of California at Berkeley, is the only ground-based HZE generator in the United States and, so far as is known, the only one in the world.

Items C, Medical Selection Factors, and D, Real Time Prognostication Techniques, are retained as goals for the future, but the present state of knowledge is such that work in these areas is not likely to be sufficiently productive for NASA purposes at this time. Consequently, NASA has no current activities in these areas.

With respect to Item E, Countermeasures, NASA is attempting to stimulate the physical sciences to give greater emphasis to shielding research, particularly to the development of mathematical transport equations for HZE ions as a means of exploring laminated materials or other new shielding techniques. NASA maintains an awareness of new developments in preventive agents, but does not conduct this research. Lastly, much of the NASA research will require space flight for confirmation and extension of the hypotheses generated. Item F, Preparation of Flight Experiments, is included to allow the early definition of such experiments as off-shoots of the ongoing ground-based research program prior to their full support from payload funds of a given flight program.

Attachment 2 is a task-by-task description of the current Radiation Effects and Protection RTOP (RTOP No. 199–45). Funding is indicated and prior years' programs are included as well.

The following is in specific reply to the four questions posed in the May 19, 1977, letter from Chairmen Stevenson and Ford:

Question. (1) What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Answer. The jurisdictional changes which have taken place between 1968 and 1977 have not caused any major problem or affected NASA responsibilities or work in the radiation area.

Question. (2) Would you please describe the nature of the contacts between your organization and State groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with State agencies? Is there any confusion concerning respecitve responsibilities of State and Federal agencies?

Answer. NASA does maintain contact with some State agencies in the radiation field and on environmental matters. The contact is primarily of a cooperative and coordinational nature by NASA field Centers. With the exception of the National Space Technology Laboratories, which is licensed by the State of Mississippi, all NASA Centers come under the purview of Federal licensing procedures. All NASA contractors come under the purview of their respective State licensing and inspection regulations. NASA is not aware of any conflicts or confusion between State and Federal agencies either directly or through its grantees or contractors.

Question. (3) Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved. Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Answer. Although there is some lack of uniformity which could be improved upon, the present regulations affecting NASA's radiation programs appear to be satisfactory. However, NASA believes the present funding levels are less than adequate. For example, shielding research has been reduced to a virtually non-functional level. Additional funding could be used in training technicians to deal with health hazards and to remedy the delays presently being encountered in amending licenses needed to conduct research projects.

Question. (4) What is your reaction to the proposals to consolidate all Federal radiation activities into one Federal radiation agency?

Answer. In NASA's view, the consolidation of all Federal radiation research activities into one agency would be a serious error. Radiation as a naturally occurring energy, of potential danger as well as utility, requires protective measures under varied circumstances and promises application to several kinds of problems. The interests and disciplines involved in these protective concerns and potential uses cannot be expected to be fully represented in one agency. For example, space radiation is unique. Ambient environments and protective requirements must be researched and fitted to the operational configuration of each flight mission. Similarly, the therapeutic application of different kinds of radiation to specific disease states must be explored under clinical conditions by the appropriate combinations of medical specialists. In both of these examples, the particular problems are properly those of the agencies involved, NASA and the Department of Health, Education, and Welfare/National Institutes of Health, respectively.

Fundamental studies of the energy, establishment of regulations for its use, regulatory authority, and certain applications, such as radiation as an energy source, could be housed in one central agency. Applied radiation problems, however, should continue to be explored by the agencies directly concerned with them.

ATTACHMENT 1—RESEARCH PROBLEMS

RTOP NO. 199-45: RADIATION EFFECTS AND PROTECTION

A. Determination of Acceptable Levels of Radiation Exposure (Responses of Living Systems and Mechanisms):
  (1) Dose—Response Relationships.
  (2) Mechanisms of Radiation Damage.
  (3) Methodology Development (for Evaluation).
B. Dosimetry of Space Environments for Living Systems:
  (1) Technique Development.
  (2) Improved Dose Expression (for Particle Radiation).
  (3) Dose Distribution Modeling.
C. Identification of Human Susceptibility Factors (Selection).
D. In-Flight (Real Time) Prognostication Techniques.
E. Countermeasures:
  (1) Preventive.
  (2) Protective.
F. Preparation of Flight Experiments.

National Science Foundation,
Washington, D.C., June 23, 1977.

Hon. Adlai E. Stevenson,
Chairman, Subcommittee on Science, Technology and Space, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

Dear Senator Stevenson: This is in reply to your letter of May 19 from Senator Ford and you to Dr. Atkinson, the NSF Director, concerning background for the June hearings on Federal radiation research and regulatory programs.

We are sorry that there has been the delay in your receiving the Foundation's answer. The delay was due, in part, to the fact that the letter was referred to a number of NSF programs in an attempt to make sure all relevant programs were queried.

This letter will confirm the telephone report I gave on June 21 to Ms. Sharon Nelson of your staff that the Foundation is not supporting research in the area of radiation health and safety research and regulation. We are, however, providing substantial support for facilities that produce radiation for research through the Division of Physics (nuclear and elementary particle accelerators) and the Division of Materials Research (synchrotron facilities). The facilities operated by NSF grantees that produce radiation are subject to monitoring for safety, but the Foundation does not get directly involved in these monitoring activities. Such monitoring is the responsibility of the grantee institution and is subject to all Federal, State, and local regulations.

We look forward to reading the statements and discussion from the set of hearings currently under way, and appreciate your informing the Foundation of your plans to hold the hearings.

Sincerely yours,

Patricia E. Nicely,
Head, Congressional Liaison Branch.

Federal Communications Commission,
Washington, D.C., June 13, 1977.

Hon. Adlai E. Stevenson,
Hon. Wendell H. Ford,
Committee on Commerce, Science, and Transportation,
Washington, D.C.

Dear Senators Stevenson and Ford: The Commission's program since 1968 in the radiation area has been primarily attending meetings held by ERMAC and other groups concerned with the problems of radiation. We have expended approximately one half a man year for each of the years from 1968 to 1975. The exception to this was a project originated in 1972 where the Office of Chief Engineer and Field Operations Bureau of the FCC initiated program XZ17. (See attachment). The man years expended on this program was approximately one. In 1976 we expended one man year. In addition to attending meetings, time was spent gathering current information on radiation hazards. In 1977 and 1978 we expect to expend between 3 to 4 man years due to the increase in correspondence and in forming any additional rules or regulations that may be required as a result of present research projects.

In response to your first question, the only change in FCC responsibility was the enactment of P.L. 90–602. The Commission in Docket 19555 Appendix 3 addressed the OSHA standard 29 CFR 1910.95.

The only contact that FCC has had with state groups was a request in 1975 from the Texas State Department of Health requesting comments on a draft of Texas Regulations for the Control of Radio Frequency Electromagnetic Radiation. The FCC did not furnish any comments. We are not aware of any confusion concerning respective responsibilities of the states and FCC.

As for present regulations, we hope that the research projects presently being carried out by HEW and other government agencies will result in a more meaningful standard than the present 10 mw/cm^2 for all frequencies from 10 MHz to 100 GHz.

The FCC does not have the expertise or resources to be able to set radiation standards relative to biological effects. However, we are concerned that radio frequency equipment operating within the limits we set to reduce radio interference may still be harmful to persons nearby. We have exchanged correspondence with several bureaus and offices within both HEW and EPA relative to possible problems should the Commission allocate additional frequencies for use in a CB-type service in the vicinity of 27 MHz, 220 MHz or 900 MHz. Those responding to our inquiries all pointed to the ANSI C95.1–1974 standard, but some feeling was apparent that this standard should be re-evaluated in light of new evidence. Additional information in the letters was occasionally confusing and/or contradictory. For example, the response from the National Institute for Occupational Safety and Health quotes a report stating that maximum power is absorbed by the human body near 27 MHz. However, a letter received from the National Institute of Environmental Health Sciences (also of HEW) states that at 27 MHz the wavelength is so long that very little energy is absorbed by the human body. There appears to be insufficient unity of thought and effort among present entities.

If I can be of further help, please do not hesitate to call on me or any member of the Commission's staff.

Sincerely,

RICHARD E. WILEY, *Chairman.*

Attachment.

Current:		
CFY + 1:		
CFY + 2:		

Project Summary: 12. Objective, 13. Approach

12. To obtain information concerning the highest levels of electromagnetic radiation existing in or near typical transmitting stations licensed by the FCC, particularly in areas where human activity is most likely to be encountered. The information derived is expected to assist in providing a basis for the Commission to determine whether an environmental safety hazard due to non-ionizing radiation may exist such that control should be established by regulation or other means.

13. Surveys are to be made in several cities to provide a sampling of data concerning electromagnetic radiation field intensities from several stations typical to those licensed by the Commission.

14. Progress: Measurements in a number of sites have been made. Recent data and analyses are presented in the following publications:
(1) J.C.H. Wang, "Power Density in Near Field of Small Linear Antennas," FCC Technical Memorandum No. 1, 1975.

(2) J.C.H. Wang and J.M. Linthicum, "RF Field Intensity Measurements in Selected Broadcast Facilities," FCC Technical Memorandum No. 3, 1976 (available by mid-November).

---

*No specific resources have been allocated for this project. Measurements and analyses are accomplished as time and ability permit during and subsequent to routine station inspection trips.

Department of Agriculture,
Office of the Secretary,
Washington, D.C., June 17, 1977.

Hon. Wendell H. Ford,
U.S. Senate.

Dear Senator Ford: The following information is furnished as requested by your letter of May 19, 1977. A similar reply is also being sent to Senator Adlai E. Stevenson.

The U.S. Department of Agriculture (USDA) does not engage in any radiation health and safety research and regulation programs from which performance standards are developed to control the emission of electronic product radiation. USDA employees, who have been authorized by the Departmnet's Radiological Safety Committee (USDA/RSC), use radioactive materials and radiation emanating equipment as laboratory tools for agricultural research and development programs and as sources of radiation for sterilizing microorganisms and insects for disease or pest control programs.

The programs are conducted in accordance with terms and conditions of licenses granted to the Department by the U.S. Nuclear Regulatory Commission (USNRC) under the Atomic Energy Act of 1954, as amended. Thus, statements and answers to the four questions relate primarily to the Department's use of *ionizing radiation* in the form of radioactive materials and radiation emanating equipment pursuant to regulations imposed by the USNRC. They do not relate to non-ionizing radiation emanating products, nuclear power reactors, fuel cycle facilities, nuclear medicine, and radiation therapy. Those naturally occurring or cyclotron produced radioactive materials not regulated by the USNRC, but used by USDA employees, are controlled by the RSC in the same manner as USNRC regulated radioactive materials.

Answers to the four questions are as follows:

1. By Public Law 93–438 and Executive Order 11834, effective January 19, 1975, the U.S. Atomic Energy Commission (USAEC) was reorganized into two agencies—the U.S. Nuclear Regulatory Commission and the U.S. Energy and Research Development Administration. The change did not affect the Department's overall efforts in the radiation area significantly as the Department continues to operate under the licensing provisions administered by the Division of Materials and Fuel Cycle Facility Licensing. USNRC. Prior to the reorganization, this Division was called the Division of Materials Licensing and was a component of the USAEC.

Before the Radiation Control for Health and Safety Act of 1968 was enacted, the USDA/RSC decided to include x-ray machines and electron microscopes among the ionizing radiation emanating equipment for which it is responsible. Appropriate acquisition procedures and radiation safety requrements were developed and implemented. Thus, the enactment of the Act reinforced the RSC's decision and facilitated the administration of its procedures and safety requirements.

2. As a Federal agency using radioactive materials and/or radiation emanating equipment, the Department is subject only to the rules, regulations, and licensing requirements, promulgated by the USNRC and is exempt from state requirements. Occasionally, a state may request a report of radioactive materials that USDA personnel are using in facilities within its borders. Such information has been furnished as a cooperative courtesy rather than a regulatory requirement. Also, occasionally confusion arises as to whether a State or Federal agency has licensing jurisdiction and related safety responsibilities. Such confusion is usually due to lack of knowledge or availability of applicable regulations and procedures and can be clarified by contacting the Radiological Safety Staff.

3. Generally speaking, the regulation of the possession and use of radioactive materials and certain radiation emanating equipment has been satisfactory. Regulations could be improved by writing them in less legalistic language so that their interpretation and application would be simplified. The time interval from the time the applicant files an application for license or license amendment to the time he receives the license or amendment is too long. The procedures for amending regulations could be improved and expedited. Since we do not know what present funding levels are, we have no comments on this matter.

4. Department procedures for implementing current radiation health and safety regulations established by USNRC involves a small staff administered by the Agricultural Research Service to monitor and maintain surveillance of all USDA programs using sources of ionizing radiation. The procedure has been administratively efficient in that all scientists in the Department involved in radiation programs can obtain guidance from one source. We recommend retention of our Radiological Safety Staff and continuation of current USDA procedures.

Several advantages for a single Federal Radiation Regulatory Agency are apparent however: all regulatory expertise would be assembled in one agency to coordinate their efforts which could result in better regulations; though many different regulations and standards have to be developed for the many different types of potentially hazardous materials, it would appear that the regulations and standards would be more uniform and consistent; more efficient cooperation with other Federal, State, and private representatives having a related interest in the development of standards and regulations; any research testing, etc., in-house or by outside public or private organizations could be more efficiently negotiated and administered.

We have confined our input to the two matrices in the programs to Agricultural Effects (Research) Plant/Animal and to Monitoring and Surveillance.

Additional information is attached to the charts. A computer printout from the Program and Resource Information System is attached to provide examples of the type of research programs being conducted in USDA.

Sincerely,

JAMES NIELSON,
(For M. Rupert Cutler,
Assistant Secretary for Conservation, Research and Education).

Enclosures.

1. Information for 1968, 1972, and 1976 was retrieved from the Cooperative States Research Service's Current Research Information System. The research data stored in the system could not be retrieved by radiation type, therefore, entries in Chart I include both types of radiation research conducted by the Forestry Service, Agricultural Research Service, and by State Agricultural Experiment Stations with Federal funds administered by the Cooperative States Research Service.

2. Information for 1976 on Chart II was retrieved from the Agricultural Research Service, Program and Resource Information System (copy attached). It does not include the research programs conducted by the Forestry Service and the Cooperative States Research Service.

A review of each project with program coordinators and research scientists provided information for identifying the type of radiation involved.

NATIONAL TRANSPORTATION SAFETY BOARD,
Washington, D.C., June 3, 1977.

Hon. ADLAI E. STEVENSON,
Chairman, Science, Technology and Space Subcommittee, Senate Committee on Commerce, Science, and Transportation, Washington, D.C.

DEAR MR. CHAIRMAN: With reference to your letter of May 19, the National Transportation Safety Board's activities do not include either radiation research or radiation regulation.

A similar reply is being sent to the Chairman of the Consumer Subcommittee.

Sincerely yours,

KAY BAILEY,
(For Webster B. Todd, Jr., Chairman).

U.S. DEPARTMENT OF THE INTERIOR,
MINING ENFORCEMENT AND SAFETY ADMINISTRATION,
Arlington, Va., June 7, 1977.

Hon. WENDELL H. FORD,
Chairman, Subcommittee on Consumers, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR SENATOR FORD: This is in response to your letter of May 20, co-signed by the Honorable Adlai E. Stevenson, Chairman of the Subcommittee on Science, Technology, and Space, concerning radiation control.

The Mining Enforcement and Safety Administration (MESA) is responsible for administering the Federal Metal and Nonmetallic Mine Safety Act and the Federal Coal Mine Health and Safety Act of 1969. The major radiation exposure under MESA's jurisdiction occurs with uranium miners. These miners are exposed to ionizing radiation from natural radioactivity. MESA promulgates standards for occupational exposure and also conducts inspections to determine compliance with such standards. We have completed the matrices that you provided in your request, but we are unable to identify the number of positions and funds expended on radiation since it is part of our overall enforcement program. Because of our inability to provide the data asked for, we have added footnotes to the matrices to explain our activities under each column.

The following responses are to the specific questions in your letter.

1. What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Answer. The Federal Coal Mine Health and Safety Act of 1969 changed our jurisdiction and operations, but this change did not affect our overall efforts in radiation areas since coal mines do not have significant radiation sources.

2. Would you please describe the nature of the contacts between your organization and state groups in the radiation field? Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and federal agencies?

Answer. Under the Federal Metal and Nonmetallic Mine Safety Act, the Secretary of the Interior is authorized to enter into State Plan agreements. Under these provisions, MESA has agreements with six States including the major uranium-producing States of Colorado, New Mexico, and Utah. There is no confusion concerning respective responsibilities between the States and MESA.

3. Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved? Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

Answer. The one deficiency that MESA views as most serious is the lack of research in the areas of detection of incipient lung cancer from radiation exposures in mining. Research in these areas has been fragmented among several agencies—National Cancer Institute, National Institute of Occupational Safety and Health (NIOSH), and Energy Research and Development Administration (ERDA). Another deficiency that makes it difficult to determine the magnitude of the problems is the lack of a better method of tracking miners that will allow an accurate determination of cancer incidence. This problem is related to epidemiology and would logically be conducted by NIOSH.

4. What is your reaction to the proposals to consolidate all federal radiation activities into one federal radiation agency?

Answer. MESA does not believe that consolidation of all radiation activities within one agency would be prudent. For example, as an occupational hazard, it is no different than exposure to any number of other toxic and harmful substances. As such, MESA can enforce standards for occupational exposure as an adjunct to inspection for other health and safety problems. Consolidation would create another Federal agency for mine operators to contend with if radiation were separated from other health and safety issues. We believe also that certain research problems, such as we have outlined above, can be treated effectively by more than one agency with proper coordination. We have had satisfactory working relations with all other Federal agencies involved in radiation regulations.

I trust the information provided herein answers your questions. If I can be of any further service, please do not hesitate to let me know.

Sincerely yours,

ARTHUR P. NELSON,
(For Robert E. Barrett, Administrator).

Enclosures.

Footnotes to matrices

1. MESA has developed standards for occupational exposure to natural radiation. These standards are based on guidance provided by the Environmental Protection Agency and approved by the President. We are continually reviewing and analyzing our standards for their adequacy and effectiveness.

2. MESA has State Plans with the States of Arizona, Colorado, New Mexico, North Carolina, Utah, and Virginia. These Plans were entered into under the provisions of the Federal Metal and Nonmetallic Mine Safety Act.

3. MESA and the State Plan States conduct a program of inspection to assure that radiation exposures do not exceed applicable standards.

4. MESA has a mandatory requirement for mine operators to report on occupational injuries and illnesses occurring among miners. Although lung cancer caused from radiation should be reported, it seldom is. Because lung cancer is a debilitating disease, mine worker victims of lung cancer usually are not employed by mining companies at the time that their disease is diagnosed. There is a reluctance by mine operators to assume liability, and such cases of lung cancer are rarely reported to MESA. The same is true of other occupational illnesses requiring long periods of latency from first exposure to recognition of disease.

5. MESA collects mine environmental data during the course of its inspections. Such data consist of radiation concentrations in working areas of active mines.

6. MESA is conducting studies of improved instrumentation and dosimetry for measuring radiation levels and exposure in mines. MESA also conducts studies on methods for controlling exposure in mines.

SMITHSONIAN INSTITUTION,
Washington, D.C., June 2, 1977.

Hon. ADLAI E. STEVENSON,
U.S. Senate,
Washington, D.C.

DEAR SENATOR STEVENSON: I am replying to your and Senator Ford's letter of May 20, 1977, requesting information from the Smithsonian on the research done in its laboratories which involve the use of radioactive substances.

The Smithsonian's Radiation Biology Laboratory uses C_{14}, Tridium and P_{32} in quantities of micro- and millicuries as radioactive tracers in botanical experiments. The total amount used each year of all three together would add to less than one curie.

The research at the Chesapeake Bay Center may use one or two tenths of a curie in a busy year, but are now using no radioactive tracers.

With reference to the questions asked, the changes in jurisdiction have had no effect on our operations. The only contact we have with state groups is when we get a routine permit from Maryland for the use of isotopes at the Radiation Biology Labortory in Rockville. We have no problem with the present regulations as they affect our use of radioactive substances and we use so little that we do not have any feeling one way or another about the proposals to consolidate all federal radiation activities into one federal radiation agency.

Sincerely yours,

S. DILLON RIPLEY,
Secretary.

DEPARTMENT OF THE INTERIOR,
BUREAU OF MINES,
JUNE 6, 1977.

Hon. ADLAI E. STEVENSON,
Chairman, Subcommittee on Science, Technology, and Space, Committee on Commerce, Science, and Transportation, U.S. Senate Washington, D.C.

DEAR SENATOR STEVENSON: This letter is in reply to your request of May 20, 1977, for information on the Bureau of Mines program on radiation research. The enclosed matrices have been completed as requested in your letter. A short description of the Bureau's radiation hazards research program is also enclosed:

Your letter requested written response to four questions. The questions and our response to them are as follows:

(1) What changes in jurisdiction between 1968 and 1977 have affected your organization's responsibilities (i.e., inception of new agencies, transfers of regulatory authority, etc.)? How have these changes affected your overall efforts in the radiation area?

Regulatory authority for health and safety in mines including radiation hazards was transferred from the Bureau of Mines to the Mining Enforcement and Safety Administration (MESA) in 1973. The Bureau of Mines retained responsibility for mining health and safety research and conducts a small research program on radiation hazards in mines. The objective of this program is the reduction of exposure of uranium miners to radon gas and its airborne daughters through the development of improved technology for the measurement and control of these hazards in mines. The Bureau is developing the testing radiation dosimeters in close cooperation with MESA with the intention that the dosimeters will eventually be used for enforcement of radiation standards in underground mines. The Bureau provides input to MESA for the development of new regulations concerning mine health and safety, including radiation hazards. MESA suggests new research projects needed for development of, or compliance with, health and safety regulations and helps evaluate proposed research projects each fiscal year using a standard methodology. Because of this close cooperation between the Bureau of Mines and MESA, there has been no adverse effect on the radiation research program due to the transfer of the regulatory authority to MESA.

(2) Would you please describe the nature of the contacts between your organization and state groups in the radiation field. Under what conditions, if any, are you required to contact or coordinate with state agencies? Is there any confusion concerning respective responsibilities of state and federal agencies?

The Bureau of Mines contacts state mine inspectors concerning any new radiation research projects which will be conduted in mines in their state. The Bureau also requests input on research needs from the state mine inspectors. There is no real confusion concerning responsibilities of state agencies and the Bureau of Mines in the radiation field, since the state agencies do very little, if any, research on radiation hazards in mines.

(3) Would you please provide the Committee with your thoughts on how the present regulation of radiation programs could be improved. Are there any present deficiencies of such regulation which you believe deserve priority attention? Do you believe the present funding levels in this area are adequate?

We believe that the present division of responsibility for mining radiation regulation and research between the Bureau of Mines and MESA is satisfactory. We recognize certain deficiencies in the determination of compliance with radiation standards in uranium mines due to a lack of accurate and reliable methods of measurement for this purpose. The Bureau is developing and testing radon daughter dosimeters which should help to overcome this problem. Development of radon daughter dosimeters is the top priority of our radiation hazards research program. Testing of the dosimeters is being done in cooperation with MESA and the Bureau will work with MESA on the development of regulations for the use of dosimeters in uranium mines. Funding for development and testing of the dosimeters is adequate. However, it is expected that implementation of the dosimeters may show that actual radon daughter levels in uranium mines may need to be reduced. For this reason increased funding for research to control radon and its daughters in uranium mines woul be very worthwhile.

(4) What is your reaction to the proposals to consolidate all federal radiation activities into one federal radiation agency?

We would be opposed to complete consolidation of all federal radiation activities into one radiation agency. Any needles duplication of effort or division of responsibility should be eliminated. However, radiation research and regulation of radiation hazards in mines is primarily a mining rather than a radiation problem. Methods for the control of radon and its daughters must fit into the mining system in a practical way so that ore can be produced economically while maintaining a safe mine environment. Radiation instrumentation must also be suitable for use under the rugged conditions encountered in mines. Radiation research in mines, as with all mine health and safety research, is best done by one federal mining research organization rather than setting up a new mining research organization in any new federal radiation agency.

I hope that the information provided with this letter is sufficient. We will be happy to provide any additional information which you may need in the course of your review of federal radiation programs.

Sincerely yours,

J. D. MORGAN, *Acting Director.*

RADIATION HAZARDS RESEARCH PROGRAM

Extensive exposure to radiation hazards found in uranium mines is a major health problem to miners. Studies indicate that uranium miners have a nonviolent death rate 40 percent higher than the normal population. The objective of the Bureau's radiation hazards research program is the reduction of exposure of uranium mining personnel to radon gas and its airborne daughters by continuing to develop improved technology for the measurement and control of radiation hazards in mines. Development of a personal dosimeter for measurement of the exposure of miners to radon daughters continues to be the highest priority task. Currently under development or test are thermoluminescent type (TLD), electronic and track etch dosimeters. It is expected that MESA will require use of dosimeters in uranium mines by fiscal year 1980. Detectors for measurement of radon and other airborne alpha emitters in a mine environment are being developed. Ultimate results of this technology is the development of (1) a radiation warning system incorporationg a BOM developed continuous working level monitor to alert mine personnel to excessively high concentrations of radon daughters in selected mine areas; and (2) a portable radiation alarm to indicate unsafe levels of airborne radioactivity. Control technology R. & D. is underway on (1) sealants and bulkheading to prevent or reduce radon leakage into the ventilation system of a uranium mine; (2) ventilation pressure control to determine the extent of radon daughter reduction resulting from deliberate cyclic pressure variation in a mine and also the relative merit of operating uranium mines at a slightly elevated pressure versus a slightly reduced pressure; and (3) air cleaning to remove radon daughters from the mine air by mechanical or electrostatic air filters. Substantial effort is being directed toward identification of major sources of radon as created by the mining cycle and development of methods to effectively control radon leakage from tailings when used as backfill in active underground mines. Furthermore, a fundamental study is being carried out to define the interaction of radon with airborne particulate matter in order to assess the effect of particulate matter on the transport of radon.

U.S. CONSUMER PRODUCT SAFETY COMMISSION,
Washington, D.C., September 16, 1977.

HON. ADLAI E. STEVENSON,
Chairman, Technology and Space Subcommittee, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: Thank you for your letter, co-signed by Senator Wendell H. Ford, in which you request information on the Consumer Product Safety Commission's radiation research and regulatory programs. We apologize for the delay in responding to your letter.

The Consumer Product Safety Commission was created in 1973 under the enabling provisions of the Consumer Product Safety Act (CPSA) 15 U.S.C. 2051. At that time, several other statutes were transferred from other agencies to the administration of the Commission. Of the acts administered by the Commission, regulatory action with respect to radiation hazards could be taken under the CPSA and the Federal Hazardous Substances Act (FHSA).

The jurisdiction of the Commission over hazards from radiation is, however, limited in several respects. The FHSA authorizes the Commission to declare a radioactive substance to be hazardous, and to require labeling or to ban the substance if labeling is found to be inadequate. Such authority is specifically limited by a statutory exclusion of any source material, special nuclear material, or byproduct material as defined in the Atomic Energy Act of 1954, as amended, and any regulations issued under that Act. Similarly, Commission jurisdiction over consumer products under the CPSA does not include risks of injury that could be eliminated or reduced to a sufficient extent by actions taken under the Atomic Energy Act of 1954. In addition, the Commission has no authority under the CPSA to regulate any risk of injury associated with electronic product radiation emitted from an electronic product if such risk could be subject to regulation under the Public Health Service Act.

Because of the statutory limitations on the Commission's authority to regulate radiation hazards, jurisdiction would appear to remain only in the area of naturally occurring substances, such as radium. Consequently, the Commission has no regulatory programs or resaerch projects relating to radiation hazards. Therefore, we have not completed the matrix provided in your letter and have no recommendations to offer regarding the questions raised in items (1) through (4) in your letter.

I hope this information will be helpful to you. If we can be of further assistance, please let us know.

Sincerely,

S. JOHN BYINGTON, *Chairman.*

U.S. DEPARTMENT OF COMMERCE,
NATIONAL BUREAU OF STANDARDS,
Washington, D.C., October 19, 1977.

WENDELL H. FORD,
Chairman, Subcommittee on the Consumer, Committee on Commerce, Science, and Transportation, U.S. Senate, Washington, D.C.

DEAR MR. CHAIRMAN: This is in response to your letter, co-signed with Senator Adlai E. Stevenson, dated September 29, 1977, which solicited comments on our current national ability to measure ionizing and nonionizing radiatio. This same letter of response is also being sent to Senator Stevenson.

You requested comments on our current ability to measure ionizing and nonionizing rediation, including areas of current weakness in our radiation measurement capabilities, and anticipated future needs. I am attaching to this letter detailed comments prepared by experts at NBS in response to your request. These comments describe the current status of the radiation measurement system and the present and future programs at NBS to develop measurement standards, expertise, and techniques to meet the needs of the system.

NBS has provided national reference standards and developed measurement methodologies for selected areas of radiation monitoring and control. The radioactivity standard reference materials produced and verified by NBS form the basis for radioisotope quality control in the Nation. Safe use of what are now low energy x-ray machines for radiation therapy (250 keV) is traceable to NBS standards. A standard source for use in industrial ultraviolet radiation applications has been developed. The measurement of electromagnetic radiation produced by distant sources, such as radar and television towers, is on a firm scientific basis.

As described in the attachments, we see the need to develop standards in fields where they do not exist, as, for example, to adequately monitor solar radiation, and to extend our capability to perform measurements from far-field regions to close to the source of radiation. However, even more important, since the need is more immediate, we must develop appropriate mechanisms to transfer these standards and capabilities to the radiation users, regulators, and researchers so that accurate measurements can be made for assurance of public safety.

Throughout these attached comments there is clear indication of substantial and growing need. One of the most perplexing specific problems is the lack of intermediate levels of dissemination through which NBS programs can reach the user level. As revealed during the hearings which your Committee held in June, this is also recognized as a significant problem by the Federal regulatory agencies. The logical structure appears to involve the states and through them to the county, city, and other user categories. Unfortunately the capabilities of state radiation control programs vary widely and appear to suffer more generally from lack of resources. It seems clear that more consideration must be given to building increased capability at the state level.

I would like to emphasize the need for a common measurement base of standards and methodologies coordinated by the National Bureau of Standards. The proliferation of regulatory agencies with interest in portions of the radiation measurement field can lead to procedural uncertainties as the manufacturer and the regulatory body monitor what is, after all, a uniquely characterizable physical quantity. For example, the Department of Defense, the Federal Aviation Administration, the Environmental Protection Agency, the Occupational Safety and Health Administration, and the Food and Drug Administration are concerned with the effects of one or another aspect of microwave radiation. The setting of a tolerable radiation level is the proper responsibility of the agency with regulatory jurisdiction. The measurement methods used to monitor the levels should be traceable to the national standards maintained at NBS.

I appreciate the opportunity to offer these NBS comments on this subject of considerable national concern. It is my hope that they will be useful in the deliberations of the Senate Committee on Commerce, Science, and Transportation. Please feel free to call on me or members of my staff for any additional information we can provide.

Sincerely,

ERNEST AMBLER, *Acting Director.*

Attachment.

NBS STAFF COMMENTS ON THE NATIONAL RADIATION MEASUREMENT SYSTEM

(Prepared in response to inquiry of Senator Adlai E. Stevenson and Senator Wendell H. Ford, Committee on Commerce, Science, and Transportation. October 13, 1977)

The inquiry of Senators Stevenson and Ford requested specific NBS comments on areas of current weakness in our radiation measurements system, existing efforts to improve our measurement capabilities, and anticipated future needs. Comments will be offered in each of these three areas for the following specific types of radiation: ionizing, electromagnetic (microwave and radiofrequency), ultraviolet, and ultrasonic. Although these four types of radiation do not constitute the entire range of NBS programs in the general area of radiation measurement, they are highly representative of the national situation regarding capability to measure radiation.

Before commenting on specific types of radiation, it would be beneficial to examine some of the characteristics of the national radiation measurements system which are generally applicable to all types of radiation measurements. Many of the weaknesses are common to the various types of radiation, and the apparent solutions to present problems also follow common lines. From our viewpoint, those solutions can generally be categorized as physical standards, dissemination mechanisms, measurement assurance, and training.

The United States is presently faced with a general proliferation of devices and materials which emit various kinds of radiation at various levels of intensity. In some cases, we know the approximate level at which significant biological hazard begins. In other cases, this level is not reliably known and remains to be determined. In any case, the critical factor is the accuracy and reliability of the measurements which form the basis for determination of public safety. The general public deserves the right to assume that the various levels of government, collectively or individually, have sufficient capability to make those measurements required to assure the benefits of radiation without undue risk. Because of severe deficiencies in the national measurement system, this assumption is too frequently unjustified.

An ideal measurement system would be based on a complete set of physical standards maintained by NBS over the range of types, energies, and intensities of radiation encountered in the present national environment. Although some of these basic standards have served the country for many years and more are under development, a significant number of additional standards are badly needed. Examples include ultraviolet, neutron, and high-energy x-ray radiation.

Dissemination mechanisms serve as the linkage between the national physical standards and the field measurements made at the level of the radiation user. This generally involves calibration of radiation sources and measuring instruments against the national physical standards, and their transfer to the user level. Through this process, adequate accuracy and uniformity of field measurements can be achieved. Since NBS is physically incapable of calibrating the large numbers of existing field instruments, intermediate levels of calibration services are required for an effective national system. One of the most serious deficiencies in the present system is the lack of organizations or institutions which can and will operate at the intermediate level.

Quality assurance for radiation measurements at the users' level is the ultimate goal of the national measurement system. Through a variety of methods which are designed to test the users' capability to make field measurements with adequate accuracy and reliability, it can be determined whether the measurement assurance programs are operational, but they reach only a fraction of the universe of national users of radiation. These programs should also be operated by an intermediate level of organizations or institutions which, in turn, could be monitored by NBS to maintain overall quality of the system.

An important consideration in the implementation and operation of an effective measurement system is the crucial role of incentives. If there is no incentive for a radiation user to have his survey instrument calibrated, or to participate in a measurement assurance program, it is unlikely that he will do so. Indeed the current sporadic nature of users' utilization of these available services supports this contention. As a result, it is not unreasonable to question the degree to which public safety is assured. Although a minority of existing regulations promulgated by various levels of government make some attempt at requiring calibrations and traceability to national standards maintained by NBS, they are ineffective because the crucial terms are never defined in a meaningful way.

Recurrence of those measurement system deficiencies which were mentioned above in general terms will be recognized in the more specific following comments on particular types of radiation.

ULTRASONIC RADIATION

Medical applications of ultrasound are becoming increasingly important in diagnosis, therapy, and surgery. In these applications, high frequency sound waves are beamed through body tissue for therapeutic purposes, or to obtain information on body tissue from the modified waves, or to destroy a region of tissue. Even though the hazards associated with ultrasonic radiation at conservative power levels are generally conceded to be less than those associated with ionizing radiation, the hazards of ultrasound are the subject of continued research. An appropriate measurement basis for accurate dosimetry is a clear need. NBS has been strongly encouraged to assist ultrasonic applications through work on standards and measurement methods by equipment and transducer manufacturers, regulators, and consensus standards-writing bodies. The proliferation, in number and kind, of commercially produced medical ultrasonic equipment represents a large and rapidly growing pressure for precise and convenient methods for measuring the fields and charactistics of medical ultrasonic equipment.

This proliferation has resulted in a proposed safety performance standard for ultrasonic therapy and surgery devices since the FDA predicts that most of the 50,000 ultrasonic therapy machines in use produce an inappropriate amount of radiation. (1) Several standard practices documents have been drafted by consensus standards organizations. One of these requires traceability to NBS standards. In a recent survey in southern Florida, the Bureau of Radiological Health found inaccuracies as great as 100 percent in the instruments used by medical personnel. (2) To obtain the desired therapeutic, diagnostic or surgical effect without toxicity, the power, intensity, and field pattern of the radiation produced by ultrasonic instruments must be known. For specific applications there is often a need to determine additionally, for example, particle velocity, sound speed, absorption, attenuation, and acoustic impedance. Some commercially-produced or laboratory-produced instruments for the measurement of medical ultrasonic field quantities have been built. A very limited laboratory intercomparison has been carried out. Careful workers have attained uncertainties believed to be the ±5 to ±15 percent range for the field quantities of power, intensity, and pressure. Uncertainties in this range are not adequate for laboratories concerned with meeting and enforcing performance standards for ultrasonic equipment, yet ±5 percent uncertainties are difficult to achieve.

The maximum allowable power outputs for various types of medical ultrasonic equipment are being set by the Bureau of Radiological Health using the best available information on the power levels at which tissue damage might occur. Every user and manufacturer will need accurate measurements to insure that equipment is operating within the established limits; therefore measurement techniques and calibration services are essential. In research on tissue damage by ultrasonics, a basic standard is essential if damage levels are to correlate between researchers.

The character of the field radiated from a ultrasonic transducer controls the quality of the measurement and the interpretation of the measurement in diagnostic applications. The character of the field in therapeutic and diagnostic applications is the point of dosimetry concerns in ultrasonic applications. Yet there are no suitable, accepted methods for determining the field characteristics of transducers or of determining the effects of the electronic which drive them.

The NBS activities which most closely address this need area include the development of measurement methods for total radiated power versus frequency, and for time-averaged total power. These are quantities integrated over the field. Measurement services based on these techniques are available by special arrangement. In addition a computer-based technique is being developed to determine the relative value of point values of the field. The techniques being developed are for continuous wave excitation for the transducer radiating into water, an approximation for human tissue. The actual application, in most cases, uses a pulsed electrica lexcitation with the transducer radiating into biological material. It is clear that this actual application is different and much more complicated to measure or predict. Also, the limited techniques presently being developed are laboratory techniques. There is a clear, immediate need for even limited portable equipment for measuring ultrasonic radiation for use in hospitals. This need has been expressed by experts from several countries.

Due to the immaturity of the measurement methods and standards system and to the present level of NBS activity, no measurement assurance programs for ultrasonic dosimetry are planned in the near term. However, an intercomparison of power measurements methods piloted by NBS is underway. Owing to the recent and rapid rise in the incidence of exposure to ultrasonic radiation, particularly state and local groups have significant concern but little expertise or background in this area. Educational programs should be considered but are not in our near-term plans.

While the present measurement needs are great, there will be additional pressures in the near future. Single-element transducers are currently the most common applicators of ultrasonic energy. However a significant and increasing usage of multi-element phased arrays is occurring. More sophisticated and systems-oriented measurement methods will be required to characterize the fields produced by these devices. Generally, there is a rapid increase in the sophistication of the electronic parts of the ultrasonic radiation devices.

ELECTROMAGNETIC RADIATION (MICROWAVE AND RADIOFREQUENCY)

Research into the bioeffects of electromagnetic radiation has been predominantly based on the premise that the thermal effect is the primary concern and therefore measurements have been tailored to look for these results. Thus adequate measurement systems don't exist for non-thermal effects research. Bioeffects experiments require a far superior design if they are to isolate causes and effects both for thermal and non-thermal effects. Long-term, low-level exposure evaluation epidemiological studies to ascertain possible cumulative effects are drastically needed; reliable measurement techniques for such studies are almost non-existent. Assuming the research identifies a need for safety standards, then the living and working environments of the general populace must be measured and mapped (a task which has special measurement requirements as a function of the closeness and complexity of the emitting sources). This will clarify the dangers of using CB or land mobile radios, repairing television and radio towers, operating plywood driers and plastic molding machines, etc. The various levels and types of responsibilities for these activities need to be clearly enunciated. Later, as regulatory and safety compliance requirements are defined, mechanisms will be needed to define measurement support to effectively implement them.

Lower levels than those believed to be thermally bio-hazardous can be severely disruptive to electronic controls upon which human life may rely, such as heart pacemakers, electronic braking controls, and kidney dialysis machines.

On a national basis, the radiation measurement system is not well defined in that researchers of bio-effects are in general not locked into an absolute base which would relate all experimental results to a common foundation. Part of the reason for this weakness is the lack of facilities and resources at NBS and the need for a deliberate program designed to assist researchers, and to educate them in the effective use of electromagnetic measurements. Measurement methods and standards do not exist or are inadequate for measuring complex electromagnetic fields such as those generated by pulsed signals, impulsive signals, and multiple-source environments.

We have a reasonable national capability for measuring average power far from emitting sources and a very limited capability for measuring close to emitting sources. To measure complex signals will require that new instrumentation be developed, together with measurement standards and ways to disseminate this capability through institutions, States, and Federal agencies. We have defined an NBS program that is addressing these needs, albeit with minimal funding. Presently, NBS research is in progress to develop measurement instruments for pulsed fields and for impulsive fields. We are also engaged in developing an anechoic chamber and TEM cells as means of developing standard measurement fields for the evaluation and calibration of instruments. Remote or unmanned monitoring instruments are also being investigated. A special temperature probe for use by bio-researchers in this field is being developed.

The current national proliferation of electromagnetic sources is significant. Examples are microwave ovens, mobile radios, industriial applications of radiofrequency and microwave heating and curing equipment, and satellite communications. The complexity of the environment is increasing and measurement of it will be more difficult as we attempt to understand its impact on non-thermal bioeffects. This will require the development of measurement standards and instrumentation capable of assessing environmental complexity. It will also require the development of simulators that can reconstruct these complex environments for bio-effects research, and that can vary the degree of complexity for determination of non-thermal effects that may be cause.

As vehicles, cars, and airplanes are fabricated out of non-metallic substances for weight savings, passengers will be exposed to more radiation from radars and natural sources such as lightning. The needs for regular environmental monitoring will be increased to assure the safety of humans from direct and indirect effects; such monitoring will have to assess the quality of the environment for waveforms, power, and possibly polarization as a function of frequency. This information will be necessary for researching the non-thermal effects on biological subjects.

Special marginal localized environments may have to be regulated and monitored frequently by States for public safety such as health conditions in restaurants are monitored. The States may need to monitor compliance with regulations by industries and users to protect consumers as weights and measures are monitored today; for example, the impulsive EM radiation from internal combustion engines which could have long-term non-thermal dangerous effects when metal bodies no longer exist on cars.

ULTRAVIOLET RADIATION

The Nation's need for increased accuracy in radiometric measurements and calibrations is being urgently felt in a variety of fields important to the economy, to the environment, and to public health. For example, the national program to predict the future world climate is in large measure dependent for its success on accurate measurement of solar radiation, both in space and on the surface of the earth. A recent interagency workshop laid out the criteria for the radiation measurements needed. That group set as minimum requirements an accuracy level of 0.1 percent for total solar radiation and 1 percent for spectral irradiance measurements from about 4 microns in the infrared to 120 nm in the ultraviolet. These accuracy levels must be maintained on the same absolute scale for a period of 22 or more years. Both requirements are well beyond the present capability of any laboratory, including NBS. The workshop has designated NBS as the only laboratory capable of developing the requisite level of accuracy, and in their report NBS was given the responsibility of developing and disseminating the measurement capability. (3) NBS must develop a technology for these more accurate measurements and must transfer it to space and field instruments.

Urgent new needs specifically for accurate UV radiometry have been created by the recent recognition that solar and artificial UV radiation pose a severe threat to both the environment and to public safety. For example, accurate monitoring of the UV transmission characteristics of the earth's atmosphere is an important long-term national problem being faced by several Federal agencies (NASA, NOAA, EPA). The inadequacy of the present national measurement system for UV radiation has interfered with the accuracy of the existing data and frustrated attempts to detect long-term trends. The climatological and biological hazards associated with possible changes in the UV transmission have far-reaching effects that include a potential increase in the incidence of skin cancer and adverse changes in agricultural production that would diminish the world's food supply. The Secretary of Agriculture recently identified ozone depletion through the use of nitrogen fertilizers, which would lead to an increase in UV transmission of the atmosphere, as one of the most important current research problems facing the nation. (4)

Also, radiation of all types is being increasingly used in our modern technological society for public benefit, while at the same time there is increasing public concern, and resulting regulatory legislation that these benefits of radiation be achieved without undue adverse impact on the public. For example, potential hazards exist for exposure to artificial UV radiation due to the rapidly increasing use of UV-rich sources in industrial processing, artificial illumination, and medical therapy.

More than 40 occupations have been identified by OSHA and NIOSH as presenting significant health hazards because of UV exposure. (5) BRH is currently developing performance standards for the UV radiation devices involved. Calibration standards from NBS will be necessary to make compliance with regulations possible in tihs area.

The NBS program plan places emphasis on the development of improved calibrations, the development of new national standards, and a systematized dissemination mechanism to transfer the radiation measurement technology to to users. The ultimate beneficiaries of the program will be the entire nation in terms of understanding future climatological trends, the general public in terms of safety from increasing levels of hazardous UV radiation, and the consuming public in terms of effective long-range plans for agricultural products.

As a short-term program, supported partially under a contract with EPA, our capabilities for source-based radiometry are being used to calibrate near-ultraviolet sources and to calibrate a radiometer which is used for studies of the biological effects of ultraviolet radiation. Our plasma spectroscopy group is developing the argon plasma arc as a portable standard for ultraviolet radiation. Calibrations of detectors and spectrometers in the far ultraviolet are being made with the NBS synchrotron ultraviolet radiation facility. New techniques based on electrically calibrated detectors and electro-optic technology are being used to calibrate silicon detectors in the near ultraviolet.

Substantially increased funding will be necessary to expand the current programs and to develop the necessary techniques and technology that will meet the urgent new requirements for transferring UV measurement capability with the needed accuracy to the national measurement system over the long term.

New ultraviolet radiation measurements milestones have been developed by NBS with extensive consultation with the Interagency Task Force on Inadvertent Modification of the Stratosphere (IMOS), the committee for Biological and Climatic Effects Research Program (BACER) of the Environmental Protection Agency, and the Council on Radiation Measurements (CORM), a group with substantial representation from the lighting and electro-optic industries. Several workshops have been held and attended to help in determining the most important goals.

IONIZING RADIATION

Although the national program for control of ionizing radiation is highly fragmented, with many responsibilities assigned to many agencies at the federal, state, and local level, the authority for enforcing compliance with the established maximum permissible levels of radiation to which the public may be exposed can only be made on the basis of measurements. For effective and equitable enforcement of regulations, these measurements must be made with sufficient accuracy and reliability. Uniformity of measurements is of primary importance for conformity between the regulator and regulatee. Thus it is essential that all field measurements have meaningful traceability to the national reference standards maintained by NBS, through a well-defined system of calibrations or measurement assurance. Unfortunately an adequate national system does not exist at this time, and most of these instruments at the user level have not been adequately calibrated. In addition, present measurement assurance programs have limited effectiveness and represent only piecemeal attempts at solving the national problem.

In recognition of this situation, NBS requested increased funding for services to state radiation control programs. In fiscal year 1975, limited funds were granted with the stipulation that initial efforts be directed toward a survey of measurement needs and capabilities in state programs. The survey was begun in February 1975 and was essentially completed in the summer of 1976. A simultaneous study was conducted by a task force of the Conference of Radiation Control Program Directors to obtain an analysis of the situation from the state perspective. Summaries of the NBS and state studies are available and copies can be provided to your Committee if desired. (6,7)

The conclusions reached by both studies were generally similar, particularly with regard to identification of major problems. The ten recommendations resulting from the task force study follow:

"1. There is a need for more direct NBS assistance to the states in the areas of physical standards and measurement systems for radioactive materials and ionizing radiation. In particular NBS should develop a mobile calibration laboratory to assist the states in both quality assurance and training.

2. NBS should provide more standard reference sources directly to the states at little or no cost.

3. NBS should review and approve all federal guidelines, standards, and regulations which require radiation measurements prior to the promulgation of such guidelines, standards, and regulations to assure that such radiation measurements are both technically feasible and practically attainable.

4. NBS should coordinate the development of model sampling procedures, chemical separation procedures, and analytical measurement methods for a variety of environmental radiocontaminants which could be used by all state, federal, and private laboratories to assure consistency in the quality of measurements.

5. NBS in cooperation with EPA should be designated as the federal agency responsible for coordinating efforts among the federal and state agencies to immediately develop a uniform data reporting system so that present environmental data which are being generated throughout the country can be utilized and evaluated in terms of possible population exposures.

6. NBS should design a model calibration facility and recommend procedures for calibration of field ionizing radiation survey instruments and monitoring systems.

7. There is a need for additional training for all State personnel involved in ionizing radiation measurements. Training programs should be sponsored and supported by all Federal agencies involved in ionizing radiation measurements. It is recommended that the Conference of Radiation Control Program Directors establish a Task Force on Training which would, as part of their efforts, coordinate the training activities sponsored by Federal agencies.

8. NBS should begin to work with specific states to resolve specific measurement problems which could be applicable to the remaining states. Such areas may include the design and operation of a state calibration facility, calibration of specific instruments for specific types of measurement problems, etc.

9. The present Environmental Protection Agency environmental radioactivity laboratory intercomparison studies program provides a cross-check on individual laboratories. That program has been very successful in identifying specific problems. However, there is presently no follow-up program to provide assistance to those laboratories which the cross-check program identifies as having such problems. The Task Force recommends that the Environmental Protection Agency, the Nuclear Regulatory Commission, the Energy Research and Development Administration, and the National Bureau of Standards cooperate in resolving this issue.

10. The Task Force was only able to scratch the surface of the problems. It is believed that a more in-depth analysis would be appropriate and may alter the above recommendations. Therefore, as a final recommendation, the National Bureau of Standards should continue to sponsor the Task Force on Radiation Measurements in a manner suitable to both the National Bureau of Standards and the Conference of Radiation Control Program Directors.

Perception of state program needs from the NBS viewpoint must be conditioned by the boundaries imposed on NBS by its legislated authority. Thus the strongest consideration must be given to those needs concerned directly with standards, their dissemination, and measurement assurance activtities. In addition, the development of standard practices must be given strong consideration.

Development of an NBS program which is responsive to state needs is being guided by the limits of NBS functions, as well as the restrictions imposed by limited resources. The latter will not allow us to develop a comprehensive program, but will enable the initiation of a limited number of pilot programs. From these limited efforts we hope to develop a foundation for future expansion.

Perhaps the clearest need discovered in the study relates to calibration of survey instruments, particularly those used for measurement of x and gamma radiation. This represents an area of major concern to state programs. Consequently we have begun a pilot program with the State of Illinois to establish an in-house calibration capability in that state program. Originally the pilot effort will concentrate on development of a calibration facility in the 50 to 120 kilovolt range, with exposures from 100 mR to 1.5 R. This is the area of interest for enforcing the Illinois regulations relating to maximum exposures of patients during x-ray diagnostic procedures. Essentially all the other states also have an interest in this area and the experience gained through this pilot program should have wide application. In addition, the Illinois calibration facility will be available to serve the needs of the surrounding states as a regional laboratory. This will be an interesting test of the concept of having a state laboratory serve as a regional facility.

In the area of laboratory analysis of environmental samples, we have begun to coordinate a project which has as its purpose to "establish more standardization in data reporting conventions including the definitions of detection limits and the treatment of results at or below these limits." This activity is consistent with the recommendations of the Task Force report. In June the first meeting was held of the subcommittee formed to address the problem. At this time, the subcommittee membership includes representatives of the states, a utility, a contractor, NRC, ERDA, HASL, EPA, HSL (Health Services Laboratory in Idaho Falls), and NBS. Subtasks have been assigned to the members, on the specific subjects of confidence level, random and systematic errors, units, detection limits, and significant figures. Assuming a consensus can be achieved, the recommendations of this subcommittee will be of value to all state programs. This project is one of nine which are included in the overall program of the Steering Committee on Upgrading the Quality and Usability of Environmental Radiation Data, sponsored by the Health Physics Society.

A third pilot program is concerned with field measurements of low-level environmental radiation. In response to a request from the State of Florida, we have begun a project which will lead to the construction of a distributed calibration source for instruments used to measure gamma levels in the vicinity of 10 μR/hr. This particular level is of interest because of the current EPA interim recommendations for gamma exposure levels at new structure sites on Florida phosphate lands. A distributed calibration source is desirable because large errors may result if a point source is used to calibrate istruments which measure distributed where phosphate or uranium mine tailings present present problems.

Other pilot programs will be added if possible within our resource limitations. Needs in state programs will continue to be studied in greater detail, and adjustments in NBS activities may be made as the result of further studies. Anticipated future needs will occur from increasing use of neutron and high-energy x rays in medical and industrial applications.

There is an obvious common theme in the above brief descriptions of the situation regarding the four selected types of radiation. There is a proliferation of radiation sources which results in increasing probability of public hazard; some of the hazards are well defined, some are not; if they are defined, regulations are issued at federal, state, and local levels; if the hazards are not well defined, research is being done to determine better definition; reliable measurements are essential to the definition of hazards and to enforce regulations; all levels of regulators and regulatees must be on the same measurement basis; that basis must be developed and disseminated by NBS; intermediate levels must serve as dissemination mechanisms; limited resources are a problem at all levels; adequate incentives are lacking in most cases; the public demands and deserves assurance of high-quality measurements at the user level. This sketches a rather difficult national problem which must receive more attention.

COMMITTEE QUESTIONS TO DARPA

Question 1. What were the reasons for classifying the research project known as "Project Pandora"?

Question 2. What was the cost of Project Pandora? What were the costs of the Walter Reed facilities and of the research projects undertaken within the facility?

Question 3. What has happened to raw data amassed during Project Pandora?

Question 4. In testimony before this Committee witnesses from the Department of Defense were unable to tell us whether or not the relevant data from Project Pandora has been destroyed or whether or not it still exists. If the data still exists, is it still classified? If the data does not exist, what happened to it?

Question 5. The witnesses testifying at the hearing tentatively guessed that the data were destroyed. If the data were destroyed, what were the reasons for its destruction? How often are documents containing data such as those involved in Project Pandora routinely destroyed? Please describe procedures for such routine destruction.

Question 6. Please provide the Committee a description of the project currently being undertaken at the Walter Reed facilities which were originally built for Project Pandora. Dr. Herbert Pollack, in his testimony before the Committee, stated that the Water Reed facilities were currently being rebuilt. Why are these facilities being rebuilt? At what cost?

Question 7. Are there now, or have there ever been, research projects on the biological or behavioral effects of non-ionizing radiation, such as Project Pandora, which have been classified?

Question 8. Does your agency see the need for such research ever again to be classified?

Question 9. Are there now, or have there ever been, research projects classified or unclassified conducted under the auspices of the Department of Defense which would have probed possibilities of utilizing microwave radiation as a form of what is popularly known as "mind control"?

Question 10. Several of the witnesses alluded to "novel utilization of the spectrum". Do you foresee the development, either by our own forces or by adversary forces, of weapons using microwaves and actively being directed toward altering nervous system function or behavior?

Question 11. Is the United States involved in developing any directed energy microwave weapons?

Question 12. Is there any evidence that Eastern Block research on microwaves is being actively directed toward altering nervous system functions from a weapons point of view?

DEFENSE ADVANCED RESEARCH PROJECTS AGENCY,
Arlington, Va., September 15, 1977.

Hon. WARREN G. MAGNUSON,
Chairman, Committee on Commerce, Science and Transportation, Washington, D.C.

DEAR MR. CHAIRMAN: Reference is made to your letter dated 12 August asking a number of questions concerning Project Pandora.

In response to these questions, the following information is furnished:

1. Project Pandora was classified in the direction of the Department of State and the United States Intelligence Board because of the sensitivity of the radiation problem of the United States Embassy in Moscow at that time.

2. The total cost of Project Pandora was $4,615,000. A detailed breakout of the costs of the Walter Reed facilities and of the projects undertaken within the facility is not available.

3. All the raw data of Project Pandora was amassed by the technical researchers with only technical progress reports of what disposition was made of the raw data.

4. This agency has available a number of technical documents identified as "Minutes of Pandora Meetings" as well as several technical reports. These documents have been declassified.

5. This agency has no knowledge as to whether the data collected at Walter Reed were destroyed and, if so, the reasons for its destruction. Documents containing research, development, test and evaluation information or data are handled by this agency in accordance with the requirements of the Federal Records Act of 1950, Public Law 754, 81st Congress, as implemented by Department of Defense Instructions.

6. Project Pandora was terminated by DARPA in March 1970 and all assets were transferred to Walter Reed Army Institute for Research (WRAIR) for disposition. Since that time, there has been no DARPA interest in the work being carried on at WRAIR and consequently we would have no knowledge as to the project currently being undertaken, or that the facilities were being rebuilt, the reasons for rebuilding and the cost.

7. With the exception of Project Pandora, this agency has not sponsored any research projects, either classified or unclassified, on the biological or behavioral effects of non ionizing radiation.

8. As stated earlier, classification of Project Pandora was a foreign relation rather than a national security matter. While it is likely that the technical aspect of such research efforts would be unclassified, the determination of a security classification must consider the potential application of the research and its effect on our national security.

9. This agency is not aware of any research projects, classified or unclassified, conducted under the auspices of the Defense Department, now on-going or in the past, which would have probed possibilities of utilizing microwave radiation as a form of what is popularly known as "mind control."

10. We do not foresee the development, by DARPA, of weapons using microwaves and actively being directed toward altering nervous system function or behavior. Neither are we aware of any of our own forces or possible adversary forces developing such weapons.

11. Although this agency is not presently involved in developing any directed energy microwave weapons, we do know that the United States, in the past, has conducted research and exploratory development on the generation of high power microwave radiation and its effects on electronic components.

12. This agency has no evidence that Eastern Block research on microwaves is being actively directed toward altering nervous system functions from a weapons point of view.

Sincerely,

George H. Heilmeier, *Director.*

Unclassified Documents Pertaining to Project Pandora

Department of the Navy,
Office of the Assistant Secretary,
(Research and Development),
Washington, D.C., December 20, 1976.

Mr. Fred A. Koether,
Defense Advanced Research Projects Agency, Arlington, Va.

Dear Fred, I am enclosing copies of all the papers I collected which were directly or indirectly part of Project Pandora. I wanted to particularly note that the Bernice Cohen paper has, in recent times, been refuted by the author's further investigations. There is no evidence in the final analysis of a correlation between radar operators and Mongoloidism.

There are other papers, but not included in this package. One that comes to mind which should probably be declassified, if not already, is a paper prepared by Janet Healer at Allied Research on a computer analysis of Soviet papers in the field, circa 1966. Also a paper by Janet Healer, myself and Herb Pollack, printed by Allied Research and submitted probably around 1970 has a pretty thorough review of Soviet literature to that time. It has been widely circulated but never officially released by ARPA.

I believe the ARPA committee report and the APL document describing the facility represent the most cogent papers written on the basic project. As you may know, when I searched for this information, I found the data books had been destroyed. There may exist one or two of Dick Cesaro's flash bulletins at the Top Secret level in the CIA archieves, but as an IDA analysis shows, these were meaningless. Various reports exist at the classified level of the actual measurements of the signal in Moscow. I don't believe these are germane, but I will be happy to give you more information if you need it.

By the way, I have included a letter to President Ford and a response signed by George Heilmeier in case you haven't run across it.

Sincerely,

SAMUEL KOSLOV,
Special Assistant for Science.

February 5, 1976.

MR. DON JOHNSON,
Oakland, Calif.

DEAR MR. JOHNSON: On behalf of President Ford, I am replying to your Mailgram of January 22nd bringing Project Pandora to his attention. This project, which has not been active for several years now, was concerned with the biological effects of microwaves and investigated the adequacy of established safety levels for normal working exposure to radio frequency radiation.

It had been suggested (wrongly, as it turned out) that new biological effects of microwave exposure might be possible, and Project Pandora was designed to test this conjecture. When it became apparent that established U.S. standards for radiation are adequate and that no new effects could be observed, the project was terminated. The Pandora experiements were never directed at the use of microwaves as a surveillance tool nor in a weapon concept. Weaponization is not feasible, and the only present surveillance uses of microwaves are in connection with rather short range radars for battlefield applications such as locating enemy vehicles at night or in fog or haze.

Sincerely,

GEORGE H. HEILMEIER, *Director.*

TELEGRAM

OAKLAND, CALIF., *January 26, 1976.*

PRESIDENT GERALD FORD,
Care RON NESSEN,
White House,
Washington, D.C.

While your staff is considering revamping the intelligence community perhaps you may want to look into the following. I have been told by people that have done research with the Department of Defense in the area of microwave that a secret project Pandora or another security program started during the Kennedy Administration involves the use of advanced microwave surveilance type of instrumentation. It is a joint Army/Navy activity.

Sincerely,

DON JOHNSON.

DEFENSE ADVANCED RESEARCH PROJECTS AGENCY,
Arlington, Va., May 20, 1976.

DR. SAMUEL KOSLOV,
Special Assistant for Science,
ASN (R. & D.),
The Pentagon.

DEAR SAM: Enclosed are copies of everything available which I believe to be useful Pandora documentation. The sources for these are the retired ARPA file and the file which IDA recently transferred here and which I have now added to the ARPA material. I plan to have the ARPA records returned to the Federal Records Center on 1 June; if you need to look further, please let me know before then. What you would see, however, is a callection of administrative paper, quarterly technical reports which are subsumed in the enclosed stuff, and a few pieces of correspondence. None of this has useful technical content so far as I can tell. Apparently, such major reports as may have been produced reposed at WRAIR and have been destroyed.

Please use the enclosed papers as you see fit, including transferring them to the Department of State if that is the logical repository. I doubt that the Secret material is worth the effort to declassify, but will leave that to your judgment. The caveats "Advanced Sensors—Limited Distribution" market d on some of the IDA material of course no longer apply; so far as I know, they never had any legal force anyway.

Again, good luck. I hope this helps.

Cordially,

F. W. NIEDENFUHR,
Director, Technology Assessments.

Enclosure.

MINUTES OF PANDORA MEETING OF JANUARY 12, 1970

Attendees.—Science Advisory Committee: Dr. Joseph E. Barmack, Dr. James N. Brown, Dr. H. Allen Ecker, Gen. Carl Hughes, Dr. Joseph Kubis, Dr. Lysle H. Peterson, Chairman, Dr. Herbert Pollack, Secretary, and Dr. Lawrence Sher.

Walter Reed Army Institute of Research: Col. Joseph V. Brady, Dr. Thomas W. Frazier, Mr. T. Daryl Hawkins, Col. Merrill C. Johnson, Maj. James T. McIlwain, and Col. William H. Meroney.

Mr. Albert Rubenstein, ARPA.

Absent.—Mr. Richard S. Cesaro, ARPA. Dr. John J. Collins, (CNO), USN. Mr. H. Mark Grove, Wright-Patterson AFB. Mr. Harris B. Stone, (CNO), USN.

I. BACKGROUND OF THIS REPORT (U)

(S) Certain events presumed to be threatening to the national interest served as a basis for ARPA's support of project Pandora. WRAIR was given funds and responsibility in early 1965 for research to evaluate the threat, since it appeared to have strong behavioral and biomedical implications. The WRAIR charter included in-house and extramural contract activities. The intramural program was largely, but not exclusively, directed toward evaluating behavorial end points using the WRAIR (special) signal on primates. The extramural support was largely biomedical.

(S) Preliminary analyses of in-house results presented by Dr. Joseph Sharp of WRAIR in 1967 encouraged the belief that the special signal altered primate behavior. Moreover, preliminary extramural cytogenetic and histological studies of the brain suggested that comparable energies were damaging to tissue.

(S) The Pandora Scientific Advisory Committee (SAC) was appointed in 1968 to provide advice for the development of the research program. The initial presentation of the in-house WRAIR data to the SAC consisted of the citation of selected cases and samples of the raw data. Requests were made by SAC for a fuller presentation of the material, since a choice of future strategies and methodology depended on the validity of the reported findings. By this time Dr. Sharp had left the Project, and an effort to be responsive to the Committee was made by Dr. James McIlwain of WRAIR. Dr. McIlwain's analyses suggested, in contrast to the initial analyses, that if the signal had an effect on behavior, it was so modest as to be obscured by effects of experimental, procedural variations, which were a result of the exploratory character of the early experimental program. Furthermore, continued extramural cytogenetic studies did not confirm the earlier reports of changes in tissue exposed to the signal.

(S) The apparent differences of initial and later experimental findings are significant from a research management point of view and should be assessed within the context of the following concurrent events:

1. The realization that research in this field is comparatively costly in equipment and effort and that large sums of money have already been allocated to equip a new laboratory at WRAIR and at Johns Hopkins University. Further, management of this highly technical facility and the experimental program requires high level behavioral, biomedical, and engineering capability.

2. Definitive research in this area will also require work with human subjects, and ethical procedures for working with humans may conflict with security needs.

3. The prescription against DOD support of basic research, unless it can be shown to have relevance to national defense and the recent general edrying up of research funds generally.

(S) In view of these considerations, research programming decisions are particularly dependent on whether the early WRAIR reports (to the effect that the signal does affect behavior) are correct or whether the later analyses refuting these reports are more credible. Because of his special competencies in statistics and experimental design. Dr. Joseph Kubis, a member of SAO, was asked to do an intensive evaluation of the procedures, the protocols, the data, and the assumptions on which subsequent interpretations of the data were made by Dr. Sharp and Dr. McIlwain.

(U) What follows in Section II is a summary and elaboration of Dr. Kubis' report agreed upon and accepted by members of the Scientific Advisory Committee.

II. THE COMMITTEE'S RESUME OF THE KUBIS REPORT (U)

(S) The earlier demonstration that the signal has an effect on primate behavior relates mainly to the procedures Dr. Sharp applied. To make the allegation credible, it should be demonstrated that a statistically significant rather than a chance difference exists between experimental and control conditions. Dr. Sharp s treatment of the experimental and control conditions can account for some part of the difference in effects. However, for understandable reasons, to be elaborated below, Dr. Sharp's evaluation did not adequately demonstrate the difference defined above.

(S) Dr. McIlwain's treatment of the data and associated experimental procedures was detailed and critical. However, if the error of obscuring an effect which may be there is to be avoided, certain additional statistical treatments are suggested. Moreover, it is SAC's judgment that any signal effects that can be teased out by further statistical treatment will, at best, be minor in comparison with effects generated by a host of procedural manipulations, some of which are intentional and some unintentional, which is characteristic of most exploratory or pilot studies.

(U) The differences between Dr. Sharp's and Dr. McIlwain's analyses are summarized below under the following headings:

(A) Assumptions and Criteria; (B) Contamination of the Control Condition; (C) Contamination of the Experimental Condition and (D) Statistical Treatment Problems.

A. Assumptions and Criteria (U)

(S) Both Drs. Sharp and McIlwain assumed that the effects (if any) of the signal on performance would be deleterious. Dr. Sharp was looking for performance impairment on any subject and in any temporal form, i.e., sudden, progressive, et cetera. This approach is advisable for an exploratory effort. However, with small numbers of experiments, subjects, and varied procedures, the dragnet approach makes the investigator vulnerable to confusing a random variation with a significant one.

(S) Dr. McIlwain assumed in most of his analyses that the effects are cumulative and that performance could be worse in the second half of the exposure period than in the first half. This is a reasonable assumption. but the data do not support this asumption of how the signal might function. The signal might indeed affect behavior and animals selectively, but if it does, then stable baselines are essential for such effects to be demonstrable. The lack of stability of the baselines is discussed later.

B. Contamination of the Control Conditions (U)

(U) Dr. Sharp's and Dr. McIlwain's approaches differed on the nature of the control conditions employed in these experiments. Dr. Sharp used baseline data obtained from all sections of the extensive experimental protocols so long as they were "after training and before exposure." Dr. McIlwain assumed that with so many changes in experimental procedures, no adequate baseline could be established. As a result his analyses were confined only to the experimental condition. As mentioned before, these analyses rested on the assumption of a cumulative effect.

(U) When changes in situational conditions produce pronounced nonexperimental effects, it is rather clear that baselines following such changes become heterogeneous. Lumping them together does not provide an adequate base for evaluating specific experimental effects. Thus, Dr. Sharp's findings cannot be entertained with confidence unless an analysis of available protocols is made to show that there are sufficient data points to provide an adequate baseline.

(S) What is critical, moreover, is the unknown effect on baselines produced by the numerous changes in the experimental environment (icebox vs. anechoic chamber, night vs. day, alone vs. with other animals, et cetera). It is a problem to determine when that baseline has reached asymptote after it has been sharply shifted by the changes in the experimental environment. When these shifts in baseline are much more pronounced than any changes by the experimental signal, one is inclined to view the effect of the signal itself either as "subtle" or of doubtful, practical significance.

(U) In addition, the cyclical nature of both the control and experimental conditions (which is necessary when working with a single animal who serves as his own control) can be self-defeating if the experimental condition produces a cumulative and permanent effect. Under such conditions the control (absence of signal) period becomes contaminated by the lingering effect of the previous experimental condition, thus making subsequent comparisons between the two conditions nondiscriminative.

(U) Under the conditions of these experiments the problem of baselines is beset with theoretical difficulties. However, the possibility of their use can be evaluated on the basis of the data available for each specific change in environmental condition.

C. Contamination of the Experimental Conditions (U)

(S) Neither Dr. Sharp nor Dr. McIlwain regarded the experimental design itself as a significantly limiting factor in the analyses of the data. Dr. McIlwani, for example, divided the experimental condition into equal time segments and tested for differences in effect between the first and second halves. There is, however, a possibility of contamination of the experimental condition in terms of its interaction with the changes in the environment under which the testing was done. Unless the interaction effect is explicitly planned for and evaluated, the experimental condition may be producing effects magnified under some conditions and reversed under other conditions so that a "deleterious" effect could be inferred in the first situation and a "beneficial" effect in the second. Such paradoxical results may be the outcome of continued analyses where the possible interaction effect has not been isolated and explained.

(U) Both control and experimental conditions could be contaminated by the presence or absence of a "weekend effect," when a significant change in the level of the background noise occurs in the laboratory. The data were not analyzed to determine whether this condition affected the experimental and control conditions differently. Similarly, equipment malfunction disrupted performance during control and experimental conditions, but no statistical analyses were provided to determine whether this was a differentially significant constraint.

D. Statistical Treatment Problems (U)

(U) Dr. Sharp's and Dr. McIlwain's approach each provided some statistical analysis of the data. Dr. McIlwain's statistical treatment was more extensive and utilized some relatively simple but effective nonparametric procedures.

(S) Dr. McIlwain seems to have shown that there are no consistent differences between the first half and the second half of the exposure period. According to his assumption that an incremental increase in effect should be expected, the results are negative. The possibility that there was an initial effect which persisted at about the same level during the exposure period is not to be ruled out by Dr. McIlwain's analysis.

(S) There are selection and computing problems associated with Dr. Sharp's presentations. On the basis of these difficulties it cannot be asserted that Dr. Sharp had established the existence of an effect due to the experimental signal. No written report has been produced by Dr. McIlwain due to the pressure of time. The conclusions herein expressed are based on limited visual examination of notebooks containing such data, charts, and graphs.

(S) From the overview available to SAC of both analytical approaches, SAC has concluded, regarding the experiments considered to date, that if there is an effect of the signal utilized to date on behavior and/or bio-medical functions, it is too subtle or insignificant to be evident.

III. SUMMARY AND RECOMMENDATIONS (U)

(S) A. The research effort mounted by WRAIR to date has been exploratory and consequently diffusely programmed. No definitive answer to the question of whether the original signal has any effect on the performance of operantly-conditioned monkeys has been provided to date. However, since no clear and strong effects have become apparent with the WRAIR signal, the findings thus far can be regarded as negative. Any plan to renew an animal (primate) study should be carefully reviewed and critically evaluated by an expert scientific and research management body.

(S) B. The WRAIR signal is composed of selected components of the original complex signal. The negative results may be considered as due to the fact that inappropriate aspects of the signal were replicated. If additional major research were to be mounted regarding Pandora, attention should be given to the original signal.

(S) C. Consideration has been given to the matter of planned human experiments using the WRAIR facility and signal. SAC concludes that, based upon existing information, there is no evidence that [no] any permanent, deleterious effects are to be expected. Also, it appears that security and ethnical questions have been resolved. However, SAC also concludes that it is likely the results of human experiments would be indistinct in the same way as those of the animal experiments. Thus, additional expensive and time-consuming human experiments might raise the same questions as raised by the animal experts, including the question of the appropriateness of the selected experimental signal. There are, however, differences between the human and primate, for example, the size and shape of the skull. Furthermore, it should be recalled that little investigation was performed in the animal experiments regarding biochemical and clinical effects. The animal experimental end points were essentially behavioral.

(S) D. A decision about whether this field as a whole warrants a high priority cannot be made in isolation from a knowledge of other problems involving threats to the national interest. SAC has not been privy to other efforts. It may be assumed that continued medical follow-up of personnel exposed to the original signal has been developed, but no details on such a follow-up have been provided. There do seem to be certain investigations which could be performed that might shed further light on possible effects of the original signal. If, however, such work is not being done, we believe it useful to support a study to consider such activities. For example, individuals assigned to selected posts are examined before they leave and at six-month intervals. The examination should include comprehensive biochemical, medical, biomedical, and psychometric performance tests that could plausibly detect any changes. A control group would be essential. If on the basis of such a systematic study significant differences appeared, we would recommend the focal research cited above be given a high priority.

Respectfully submitted by Lysle Peterson, Chairman.

INSTITUTE FOR DEFENSE ANALYSES,
Arlington, Va., March 31, 1970.

MR. RICHARD S. CESARO,
OSD/ARPA/Advanced Sensors, Pentagon,
Washington, D.C.

DEAR MR. CESARO: The minutes of the Pandora meeting of January 12, 1970, contain a grammatical error of a double negative on page 6, paragraph C, line 2.

The sentence should read, "SAC concludes that, based upon existing information, there is no evidence that any permanent, deleterious effects are to be expected" rather than "SAC concludes that, based upon existing information, there is no evidence that no permanent, deleterious effects are to be expected."

Yours truly,

MARILYN CHANDA,
Secretary to Dr. H. Pollack.

Date: January 14, 1969. Memorandum to: Mr. R. S. Cesaro, ARPA. From: IDA Review Panel. Subject: Flash Report on Pandora/Bizarre Briefing (S).

(S) In response to a request from Advanced Research Projects Agency (ARPA), a special panel was convened by the Institute for Defense Analyses (IDA) to review the research techniques, results to-date, and to make recommendations for the future of the Pandora/Bizarre program.

(S) The IDA Panel personnel were as follows:

1. Lysle H. Peterson, M.D., (Chairman) Univ. of Pennsylvania.
2. Joseph E. Barmack, PhD, C.C.N.Y.
3. Joseph F. Kubis, PhD, Fordham University, N.Y.
4. BG Frederic J. Hughes, M.C., Walter Reed Gen. Hospital.
5. Herbert Pollack, M.D., Institute for Defense Analyses.

(S) Observers present were:

1. Richard S. Cesaro, OSD/ARPA/AS.
2. James P. Deck, Colonel, Wright Patterson AFB, AFAL.
3. Daniel J. Sullivan, OSD/ARPA/AS.

(S) The briefings were presented by:

Col. J. Brady, M.S.C.—WRAIR.
Maj. J. Sharp, M.S.C.—WRAIR.
Capt. McIlwain, M.C.—WRAIR.
Mark Grove, AF Avionics Lab—WPAFB.

(S) The panel met at 0900 on Friday, December 20, 1968, in the Forest Glen Annex of the Walter Reed Army Hospital. All persons present who had not done so previously signed the Pandora/Bizarre clearance forms. Briefings and an inspection of the physical plant lasted until 1230. The panel and the briefing team drove to the Institute for Defense Analyses where they reconvened at 1300 hours. Further discussions were carried on until 1500 hours, when the panel thanked the briefing team and went into executive session.

(S) The terms of reference for the review panel as presented by Mr. Cesaro called for an initial flash report based upon the briefings of the day. Mr. Cesaro indicated that he expected the panel to operate on a continuing basis until the project was completed. It is expected that the panel would be enlarged in the near future as soon as clearance procedures permitted.

(S) The flash report was to be the response to the following questions posed by Mr. Cesaro:

1. Does the panel consider the research procedures reported at this briefing scientifically sound and capable of supplying the data required to satisfy the stated objectives?
2. Does the evidence presented support the stated deductions or conclusions?
3. What future plans and procedures should be adopted in view of the findings to-date?
4. Does the panel consider it necessary to develop a "real time" data processing technique to facilitate the identification of those components of the "synthetic signal" which are responsible for the observed biological effects?
5. Does the panel wish to express an opinion as to the mechanism of the action of the electromagnetic radiation on the intact animal?

(S) The panel was unanimous in its opinion that the use of multischedule programs for operantly conditioned monkeys was a sound and acceptable technique to assess degradation or acceleration of work patterns. That the monkeys exposed to the specific "synthetic Moscow signal" in field strengths from 1 mw/cm^2 up to 4.6 mw/cm^2 showed degradation of work performance after 10-hours-a-day exposure for from 11 days to 21 days. This degradation in performance may be regarded as a "vigilance function degradation." The effects appear to be grossly functionally reversible. There is some evidence that repeated series of exposures sensitizes the animal and shortens the latent period before signs of vigilance degradation appear.

(8) The WRAIR investigators attempted to develop techniques with more rapid response times in the hopes of being able to facilitate the identification of the elements of the synthetic signal responsible for the bio-medical effects. These took two directions. One was a study of alteration in reaction time response in the primates after exposure to the micro-waves. The other was to implant a series of specially designed electrodes into specific areas of the brains of monkeys and to record the electro encephalographic changes before and after radiation.

(S) The studies on reaction times are inconclusive to-date. More data would be needed to express an opinion as to whether this approach should be pursued further or discarded.

(S) The E.E.G. approach has been carried out in association with The Brain Research Institute at the U.C.L.A. School of Medicine. The problem of artifacts and analysis of wave forms makes interpretation difficult. Further work in this area should be supported. To do this effectively, the analysis of the E.E.G. recordings should be on a "real time" or approximately "on line" analysis. This will require a computer availability and capability. The computer may be an in-house special purpose one, or a connection with a central computer programmed for this analysis. A cost effectiveness assessment of the alternatives should be helpful in the decision.

(S) The panel was of the opinion that the help of Dr. John Tukey of Princeton should be obtained. He is considered an outstanding expert in the field of wave form analysis.

(S) The WRAIR research workers presented two additional facets of the work. These were attempts to determine if there were any detectable morphological changes in the tissues. One effort was directed toward a study of the chromosomes of the circulating blood. The two animals studied to-date were reported as showing no changes.

This phase should be continued until a sufficient number of animals have been studied to give positive assurance that the non-ionizing radiation does not have any effect on chromosomes. The other was the histo pathological studies of the central nervous system tissues taken from animals that had been radiated. This study is being carried out at Tulane under contract. At the time of this briefing only one monkey brain had been studied. The contractor had reported that this brain was "different" from the controls. (The study is a blind one to avoid prejudice.) In view of the suggestive but inadequate evidence, additional effort must be made to further this aspect of the program.

(S) The panel recognizes that Col. Brady is a professional leader in the field of animal behavior studies and has added substantially to the credibility of the work.

(S) The response to Question #3 takes into consideration the total problem, including the animal findings as presented, and the time and cost element in extending animal studies to provide a more complete spectrum of response. In the absence of significant adverse findings in the chromosomal and histo pathological studies mentioned above, the future course of action must include a study of human response to non-ionizing radiation in low level fields and with the specific modulations employed in the primate exposure tests. Animal studies are only able to provide a limited spectrum of responses. The human with his ability to describe subjective changes can extend the response gradient through the levels: (*a*) Feelings, attitudes, fatigue, moods, etc., (*b*) Health, physical and mental, (*c*) Performance and stamina.

The animal studies are focused on (*c*) but may include (*b*); they cannot measure (*a*).

(S) Over a period of years humans have been exposed to micro-wave radiations at much higher field strengths than are proposed in this work. The U.S. personnel in the Moscow Embassy have been exposed to the micro-wave signal over a period of many years. The panel were not given any evidence of impaired health of these people.

(S) A protocol should be developed with the following objectives:

1. To determine the immediate or short time effects on humans of the synthetic Moscow signal in use at W.R.A.I.R. on the three aspects mentioned above. This should be given a high priority.
2. To provide for followup observations of the subjects.
3. The study should contribute to the understanding of the effects of micro-wave radiation on man in general as well as the specific Moscow signal.

(S) The protocol should be developed by the responsible group. This panel will stand ready to review the proposed protocol and offer such advice as they see indicated when asked to do so.

(S) It is suggested that the program provide for:

(*a*) Biochemical laboratory analysis of blood and urine for a variety of substances including steroids, enzymes, trace metals, etc.

(*b*) Cardiovascular evaluation such as E.C.G., blood pressure, etc.

(*c*) Chromosomal studies of lymphocytes cells.

(*d*) Appropriately sensitive and reliable studies on behavior.

(S) Subjects selected should be normal, healthy, young male adults. Exposure periods should be at least 90 days unless significant changes occur earlier. Subject should be divided into 3 groups:

1. Controls
2. Subjects with a history of exposure to micro-waves.
3. Subjects with no previous exposure to micro-waves.

(S) The panel at this time has no basis upon which to suggest the mechanism involved.

(S) It is recognized that the findings to-date were presented to the panel in an orientative way and the format of the presentation was qualitative. The panel suggests that the date be prepared in a statistical format for better scientific evaluation. The panel would like the opportunity to examine the data in depth.

LYSLE PETERSON.
JOSEPH KUBIS.
JOSEPH BARMACK.
FREDERIC HUGHES.
HERBERT POLLACK.

ADDENDUM

January 17, 1969.

The final results of the examination of the chromosomes obtained from the peripheral blood of one monkey, previously irradiated with the "Moscow signal" at a field strength of 4.6 mw/cm ^{2}, indicate marked aberations in 40 percent of the cells. The tests are being repeated.

MINUTES OF PANDORA MEETING OF JANUARY 17, 1969

Present a.m. and p.m.—Science Advisory Committee: General Frederic J. Hughes, Jr., Dr. Joseph F. Kubis, Dr. Lysle H. Peterson, Chairman, Dr. Herbert Pollack.

Walter Reed Army Institute of Research: Colonel Joseph V. Brady, Dr. Thomas W. Frazier, Major Joseph C. Sharp.

Dr. Joseph E. Barmack absent due to illness. Mr. H. Mark Grove, Wright-Patterson AFB. Commander Hugh S. Pratt, MC, USN (C.M.D. USS Saratoga). Rear Admiral Frank Voris, MC, USN.

Present p.m. only.—Dr. Joseph M. Aein, IDA, Mr. Richard S. Cesaro, OSD/ARPA/AS, Dr. James T. McIlwain, MC, USA, WRAIR, Mr. A. Rubenstein, OSD/ARPA/AS.

1. Dr. Pollack reviewed considerations relative to the USN–ARPA study to be carried out aboard the USS Saratoga currently in Philadelphia Naval Yard in preparation to join fleet operations.

2. Rear Admiral Voris and Commander Pratt commented on operational considerations of the study from money point of view.

3. Colonel Brady, Dr. Frazier, and Dr. Sharp commented regarding Walter Reed army considerations.

4. Mr. Grove commented regarding physical measurements and engineering considerations of shipboard radar measurements and monitoring.

Summary of Discussions.—Dr. Pollack reviewed need for definitive data on effects of radiation on physiological and psychological (particularly behavioral) functions in man. Primary areas to be looked at appeared to be (a) physiological, (i) formed blood elements, i.e., genetic alterations, (ii) cardiovascular and (iii) neurological and (b) psychological regarding task performance and group behavior. Regarding general plan involved selecting a population of ship's crew subjected to shipboard radiation (radar) and to compare them with a group below decks and not exposed to radiation. It appeared that plane handling crews on the hanger decks and flight decks involved similar enough tasks and living conditions that comparisons could be made so as to reveal any major or gross differences. Dr. Kubis and his team with the support of Commander Pratt and his staff aboard ship would review the personnel records of the two crew populations and select from them appropriate groups. They would receive physical and psychological tests during the approximately two weeks that the ship was scheduled to be docked in Philadelphia. Repeat tests would be made at intervals while the ship was underway and at certain scheduled ports-of-call during the following six weeks, a specific protocol was to be developed.

Discussion centered on selection criteria and upon what tests would be given to the selected groups.

Physical examination (including a general physical exam):

1. Blood specs for leucocyte genetic evolution
2. Blood pressure and pulse rate (on arising and after work cycle)
3. Discussion related to sending selected representation to the Philadelphia Naval Hospital for EEG evaluations. Also, a "microneurological exam" was described which might be included

Psychological examination was designed by Dr. Kubis and associates. Dr. Kubis indicated procedures would relate to cognitive, psychomotor, physical efficiency and sensory perception testing.

Three phases to protocol: I. Dockside—two weeks. II. Toward end of ten day shakedown. III. Three to six months later.

Meeting adjourned at 4:30 p.m. on January 17, 1969.

Minutes respectfully submitted by Lysle Peterson, Chairman.

SUMMARY OF PANDORA MEETING HELD: APRIL 21, 1969

I. Detailed minutes attached. Same classification and instructions.

II. Meeting organized in three parts:

1. Review of "Big Boy"

A. *Purpose.*—Elucidate effects on man of microwave radiation (radar) by comparing ship's crew groups apparently exposed to radiation to groups protected from radiation (below deck and remote stations). Studies on *USS Saratoga* in two stages (i) dock side in preparation for shakedown and (ii) shakedown, i.e., underway and operational.

B. *Findings.*—No significant differences in psychological tests performed on the apparently exposed and control groups. Also, no apparently significant differences on genetic (leucocyte) and physical findings. Thus, studies generally proved negative. Detailed report due from Dr. Kubis.

C. *Radiation Findings.*—Detailed survey of on-board radiation levels revealed that levels were considerably lower than anticipated, i.e., in most cases levels varied from 0.3 to 0.03 mw/cm^2 and in no case greater than 1 mw/cm^2. Radars were operating 80 to 90 percent capacity.

D. *Summary and Conclusions To Date.*—Saratoga study verified testing procedures and provided useful information for developing human radar-field testing. However, studies were negative since exposures were very low.

2. General discussion of ARPA contracts relative to biomedical effects of microwave

A. Dr. Brazie's studies of CNS tissue exposed to microwave radiation reviewed. *Recommendations:* to accelerate contractor's efforts as urgent and to extend samples. Attempt to get reports from contractor for inclusion in general report to panel as soon as possible.

B. Contract with Dr. Ross Adey reviewed. *Recommendations:* Although Dr. Adey's efforts bear on the general problem of the effects of radiation and fields on CNS functions, they are not directly contributory to priority ARPA questions. Since he is furnishing valuable EEG evaluation services as well as contributing to the general field, it was suggested that he be encouraged to deal more directly with priority questions and also to continue support for present. As Walter Reed capability develops, if contractors interests tend away from ARPA interests, support should be phased out.

C. New England Institute for Medical Research (Dr. Heller) program regarded as not contributing directly to ARPA high priority question although the contractor has capabilities in the area.

D. Work at Milton Zaret Foundation attempting to confirm or reproduce U.S.S.R. work. Review for information to panel.

E. The Lilienfeld studies conducted several years ago were reviewed, since a new proposal was being developed to extend the earlier studies. It was concluded that, due to the size of the Baltimore area mongoloid population and incidence, the scope of the study could probably not be increased by more than 50 percent. It was recommended that (i) scope not be extended beyond the Baltimore region, e.g., Washington area, (ii) that the program be regarded as a multiphase effort and that Phase 1 should be funded. If findings of Phase 1 indicated that further studies would be promising, then later phases could be considered for funding. Thus, proposal should include in-depth follow-up of original cases as well as new cases uncovered. See detailed minutes.

F. Studies of Dr. Dordano (Johns Hopkins), Dr. Sol Snyder, and Dr. Justison were reviewed for information.

3. General discussion

A. Priorities of ARPA interests in the microwave field were reviewed. High priority still assigned to evaluating the significance of Moscow Signal and also, in the general context, the biomedical effects of microwave radiation on humans such that meaningful safety standards can be set.

B. It was agreed that there is at present insufficient evidence to draw conclusions. In answer to questions about whether or not other studies (aside from those supported by ARPA) are likely to or have shed light on the problem, it was concluded that the only known study not included herein was that of Dr. Jacobson (George Washington School of Medicine) on young women exposed to Moscow Signal. Findings may indicate abnormal genetic activities in some of the women. Significance is not established. There was general discussion of chromosomal aberrations and its causes.

C. It was recommended that further studies be developed: (1) Walter Reed facility and program advancement be encouraged. Extend animal studies and initiate human studies. Suggestions for protocols were made, e.g., study include four men involved for six to eight months. Study to be in two groups and double-blind. (2) Programs to be developed to take advantage of land-based radar installations.

4. It was recommended that the Walter Reed group prepare and present a detailed review of the field, i.e., their activities with reports of their findings, protocols, etc., since projects were begun. Also, a review of relative contract work supported by ARPA and related to Walter Reed efforts as well as any related studies of others in field.

Respectfully submitted by Lysle Peterson, Chairman.

DETAILED MINUTES OF PANDORA MEETING OF APRIL 21, 1969

Present.—Science Advisory Committee: Dr. Joseph E. Barmack, Dr. H. Allen Ecker, General Frederic J. Hughes, Jr., Dr. Joseph F. Kubis, Dr. Lysle H. Peterson, Chairman, Dr. Herbert Pollack.

Walter Reed Army Institute of Research: Colonel Joseph V. Brady, Dr. Thomas W. Frazier, Mr. T. Daryl Hawkins,[1] Colonel Merrill C. Johnson, Major James T. McIlwain.

Mr. John F. Collins (CNO), USN.[1] Mr. H. Mark Grove, Wright-Patterson AFB. Mr. Albert Rubenstein, ARPA. Mr. Harris B. Stone (CNO), USN.

Dr. Pollack reviewed events since previous meeting. He noted the formation and meeting of a new committee (ERMAC**) from the Office of Emergency Planning and chaired by General James D. O'Connell to consider microwave radiation. This panel resulted from legislation setting HEW as the responsible agent for microwave radiation health considerations. He also noted that a document had appeared by Mr. Rexford Daniels under contract to the Office of Telecommunications Management. This document has been classified. He then noted that "Big Boy" shipboard exercise had been completed insofar as the dock-side and shakedown cruise activities aboard the *Saratoga*. Dr. Kubis would be submitting a report of activities and findings to date.

Dr. Kubis reviewed "Big Boy" objectives and events to date:

A. *Objective:* To study certain behavioral and physical functions of selected crew aboard the *Saratoga* in order to ascertain effects of microwave radiation on man regarding shedding light on effects of Moscow Signal, i.e., nonthermal effects (if any) of radiation of radar origin.

B. *Procedures:* 1. Three groups of ship's crew were selected:

(*a*) Flight deck crew (eight in number). Highest levels of exposure expected.

(*b*) Hangared deck crew (fiifteen in number). Low levels expected.

(*c*) Look-out crews (eight in number). No exposure expected.

2. Dock-side control tests conducted from Jan. 27 through Jan. 30, 1969. Five-man team under Kubis with excellent cooperation of naval medical personnel. (Details will be included in Dr. Kubis' report.) Batteries of tests included performance (e.g., aiming, depth perception, etc.) and written procedures. Also, base-line physical exams were given.

3. *Seagoing* tests were performed while ship was under way for shakedown cruise Jan. 30, 1969, through Feb. 10, 1969.

4. *Summary.*—Sixty-seven tests were performed in three days at dock-side, and ninety-two tests were performed at sea. Forty-seven tests represented retesting of control material. There were a number of disturbances regarding shipboard routine, etc., e.g., high noise levels, P-A system interrupted activities in "quiet room," general quarters intrusions into test areas due to routines variable

---

[1] First attendance.

line voltage which affected equipment. Three dock-side test days conducted by five-man team; eight sea test days conducted by three-man team. It was regarded by Dr. Kubis that the testing was satisfactory and that the interruptions were not significant. Most test procedures were good (0.9); some were poor (greater than 0.1).

5. *Findings.*—There were no significant differences in the dock-side tests, i.e., among groups, and there were no significant differences among groups in the under-way tests, i.e., about 50 percent showed some increases in performance scores and about 50 percent showed some decreases. It was recommended that isolated power supply for instrumentation be developed if further work is to be done aboard ship.

Mr. Mark Grove reviewed the measurements and monitoring of shipboard radar levels. The ship was swept re two primary radiation sources, i.e., SPS–30 (S-band radar) and SPS–43 (UHF) search radar. It was expected from a naval electronics lab report that there might be greater than 10 mw/cm^2 on at least 80 percent of the surface of the deck (data from destroyers). Mr. Grove and Dr. Kubis were on ship at the same time but worked independently. Used RAMCORE dosimeter, HP power meter with thermoistor bridge (re S-band) from island to bow, 9 decks.

Findings.—In no case did measured levels exceed 1 mw/cm^2 with radar operations at 80 to 90 percent of utilization rate. Ranges of findings were in most cases less than 0.3 to 0.03 mw/cm^2. It was noted that verbal reports from shipboard engineers, i.e., engineering center and ship's hazards group, had indicated these findings. It was suggested that such reports had been made to the SEC.

C. *Discussion:*

1. Cover story considered appropriate and worked well (Robert Stone).

2. Aircraft radar and HERO effects were discussed. Effects and indications were insignificant.

3. Radiation from radar generators considered, i.e., 50 to 100 KV X-ray generation from tubes. Considered that lead shielding was adequate.

4. Mr. Rubenstein indicated that there were several excellent land-based radar sites which might be appropriate as study sites.

5. Blood studies from Saratoga crew were discussed. Colonel Johnson reported that twenty-one samples were recovered at San Juan. Seventeen successful cultures obtained with 288 spreads photographed. These were coded for double-blind studies. Code not yet revealed. Although two abnormalities were found, they were regarded as in normal range.

6. Several discussions of genetic aberrations of leucocyte nuclei covered several areas:

(*a*) Colonel Brady's three monkeys exposed to date at Walter Reed (thirty days) to special signals. One of these was the initial one showing abnormal chromosomal changes. Plan now is to get samples during exposure and with larger group of animals.

(b) Dr. Pollack reported the studies of Dr. Jacobson at George Washington University who has studied young women returning from embassy in Moscow (State Dept. contract). One hundred forty blood samples were examined over a four-year period of time. These specimens were identified only by code numbers. Four of these reportedly showed serious chromosomal abnormalities. Colonel Johnson reviewed these reported findings with Dr. Bender of Oakridge. The latter expressed the opinion that the evidence was based upon weighted data which may not be acceptable to all experts in the field.

(*c*) Dr. Johnson described the general character of chromosomal abnormalities re probabilities, stillborns, mongolism, chemicals, and drugs, etc. It was described that while bone marrow testicular tissue etc. might be better tissue to study (higher rates of replication), most knowledge is based upon leucocyte studies.

(*d*) The older Lilienfeld (John Hopkins) studies were of Korean and WW II veterans relative to the incidence of mongoloid children born to them. It was concluded that the earlier study was not well designed to reveal data regarding current interest. Study indicated that eighteen of twenty-five mongoloid children had fathers who had been exposed to radar. It is now proposed to expand the study in Baltimore and possibly in Washington. It is likely from the incidence and population of mongolism that the number cannot be increased beyond 50 percent, i.e., from twenty-five to about thirty-six. It was suggested that the original twenty-five and additional cases should be studied in detail, i.e., cytogenetic studies of testicles and lymphocytes. It is also concluded that the study may not answer the question. It was proposed that the study should cost $100,000; $50,000 from ARPA and $50,000 from NIH. The objective should be to validate the earlier study; i.e., cross-validation seems appropriate. The study may be regarded as in three phases. Phase 1 may be supported. Later phases should not be funded unless Phase 1 defines an appropriate study, i.e., a milestone decision should be made.

General discussion concluded that additional work is required to investigate whether or not appropriate radiation levels and type have genetic effects on man. Shipload versus land-based studies were discussed. It was concluded that land-based radar studies should be seriously considered and planned if appropriate. Details of George Washington University study were lacking to the group.

8. Dr. Brazies' (New Orleans) studies on material sent from Walter Reed are not completed as yet. Contractor does not know what the exposure is nor in which animals. (Does know that it is microwave.) He reported that one monkey (exposed to special signal) showed significant changes in the auditory and visual cortex but not in deeper structures. He is now studying two other monkeys and four dogs. These reports are due this year.

It was concluded that the contractor should be urged to proceed as rapidly as possible, i.e., with urgency.

9. It was concluded that more animals should be exposed and studied. There was discussion of the new facilities developing at Walter Reed. They are expected to be completed soon.

10. Contract with Dr. Ross Adey reviewed. Adey's studies have been concerned with modulated A.M. (3 to 10 cps) and C. W (4.6, 2 v/meter) and S–band radar modulated with EEG. He is continuing monkey studies regarding EEG and reaction-time. He has a contract with Northrup for the study of reaction times in electrostatic fields. It is felt that, although Dr. Adey's work is not directly concerned with the important questions of the effects of VHF on CNS function and that of excluding the electrical effects as artifacts, his work is related to the general field of the effects of radiation and CNS function. Also, he is assisting Walter Reed with EEG evaluation and data processing. Current level of support is about $135,000 annually. It was concluded that Dr. Adey should be informed that his own priorities and work trends are not entirely matched with those of ARPA. Although his work is related to the general field and is of considerable assistance to the Walter Reed effort, it is thought that his support might be phased out in a year or two after the Walter Reed facility is better developed.

11. A contract already funded by ONR with New England Institute for Medical Research (Dr. Heller) was reviewed. It was suggested that the content of this work is not directly appropriate to this subject although that institute has a microwave facility.

12. A contract with the Milton Zaret Foundation of Scarsdale, New York, was reviewed. Contractor also uses facilities of Brooklyn Polytechnical Institute. Work primarily in 700 p.p.s. (1–10 u. sec.) range. Is attempting to confirm or reproduce Myrra, Czechoslovakia, work, i.e., production of differences in heart rate at subthermal levels, This review was for information.

13. Other contracts were also reviewed: (*a*) Dr. Dordano of Johns Hopkins in A. M., F. M., C. W., S-band frequency work on monkeys. (*b*) Dr. Sol Snyder of Johns Hopkins is studying neuropharmacological effects, e.g., turn-over rates of norepinephrine and serotonin. (*c*) Dr. Justison (Kansas City, Missouri) using microwave Tappin oven is studying hypnotic and soporific effects of low power level microwaves. It is thought that the geometry of the oven may provide higher power levels than predicted.

14. It was estimated that current funding in the area is $500,000 outside and $200,000 in-house (does not include reconstruction and development costs at Walter Reed or computer facility).

15. It is regarded that the new facility providing three chambers and data processing including (Hewell Packard) general purpose computing, record and reproduce capability for time series, coherence, cross-and auto-correlations, etc., real time capability will be ready between mid-June and August.

16. The priority of questions of interest to ARPA was discussed. It was reiterated that the elucidation of the Moscow Signal remains as a high priority question with the general field of the effects of microwave radiation on man in order that safety standards may be rationally developed. It was also noted that, aside from the work of Dr. Jacobson, there was apparently no other relative work being conducted by Federal agencies.

17. The need for information on humans in addition to the accelerated animal studies at Walter Reed was emphasized. Therefore, it was urged that the Walter Reed facility develop a human program and start immediately to develop Phase 1, i.e., to develop a plan and protocols.

(*a*) Suggested putting the human aspect into the Pandora program rather than in the Walter Reed stress program.

(*b*) Estimated that human subjects would be required for six to eight months and that they could be obtained from Ft. Dietrich.

(*c*) Controls should also include as many variables as possible including IQ, memory and performance testing. Control period should be less than sixty days. One or more should go through the entire procedure without exposure, and one or more with alternating exposure plan. Study should be double-blind with protection of eyes and gonads. Shielding of testicles is recommended.

(*d*) Panel would like to review protocol before enactment.

18. Land-based radar station human study program should be developed to replace or supplement any onboard studies at sea.

Respectfully submitted by Lysle Peterson, Chairman.

MINUTES OF PANDORA MEETING OF MAY 12, 1969

Present.—Science Advisory Committee: Dr. Joseph E. Barmack, Dr. H. Allen Ecker, General Frederic J. Hughes, Jr., Dr. Joseph F. Kubis, Dr. Lysle H. Peterson, Chairman, Dr. Herbert Pollack.

Walter Reed Army Institute of Research: Colonel Joseph V. Brady, Dr. Thomas W. Frazier, Mr. T. Daryl Hawkins, Colonel Merrill C. Johnson, Major James T. McIlwain.

Dr. John F. Collins (CNO), USN. Mr. H. Mark Grove, Wright-Patterson AFB. Mr. Albert Rubenstein, ARPA.

(S) The primary order of business was the preliminary protocol proposal for human studies which was requested at the previous meeting on April 21, 1969. The protocol had been distributed toward the end of the previous week and, therefore, had not been received by many of the panel. Time to pursue the proposal was taken before discussion began.

(S) Dr. Brady noted that the proposal had been the combined effort of himself, Thomas Frazier, Merrill Johnson, and Daryl Hawkins and desired the advice of the committee on the ninety-day protocol. Dr. Brady noted that they had considered two basic strategies: (i) assumes that there is an effect of the signal (based upon previous experience) and the protocol is designed to maximize the yield and (ii) assumes that there may or may not be an effect (nue hypothesis) and the protocol would include "extreme" operations, i.e., high-forcing functions and large "n"s. If an effect is seen, then fine responses are defined.

(S) In view of previous experiences and evidence available, the first alternative was chosen, i.e., based upon the assumption that there is an effect. Therefore, protocol is an attempt to optimize economic considerations, use small "n"s and primarily to define the effects of the signal.

(S) The panel discussed the over-all strategy and alternatives and agreed with Dr. Brady. Also, re human experiments, this approach regarded most defensible as a prerequisite to more demanding studies, if needed.

(S) It was noted that a major question regarding any such study relates to the evaluation of behavioral effects since the spectrum of possibiilties is so broad compared to physical evaluation. Thus, the major part of the discussion related to behavioral aspects of the program. It was also noted that any energy form, if large enough, will produce biological effects. It was agreed that the signal used would be the special signal at the levels developed and used with the primates, i.e., between 4.5 and 5 mw/cm^2. Discussion revealed several distinct questions:

(i) Because the "n" is small (eight subjects) there, the question was raised as to whether the protocol will permit the characterization of the group, i.e., significance of the findings in individuals in a small "n" group.

(ii) To what extent is the instrumentation appropriate to carry out the objectives of the experiment, e.g., signal beam incidence, range of power levels, polarization, etc. The protocol had not detailed the electromagnetic aspects of the experimental design. Also, what are the effects, if any, of the signal on the instrumentation, e.g., EEG electrodes?

(iii) What are the dependent variables re behavior?

(iv) What are the considerations relative to monitoring the physical (biomedical) parameters re two purposes: as a monitor of the subject's general health and as scientific data re effects of signal?

(v) What are the classification considerations of the program re its management and scientific effectiveness?

(S)The discussion provided consensus regarding these points as follows:

DOD regards the general line of effort to aquire human-based data on effects of the signal, with appropriate safeguards, as a high priority. ARPA believes that the entire effort should be classified for several reasons. It was urged that DOD provide written security specifications and guide for the program.

(S) An appropriate cover relates to the purposes of the program to evaluate the validity of U.S.S.R. reports that nonthermal effects of nonionizing radiation are significant.

(S) It is urged that the special signal (or any improved signal, i.e., to better simulate the Moscow signal) be used. Currently, special signal-producing available equipment can develop less than 10 or 20 mw/cm^2. Monkey studies have been done at 4.6 mw/cm^2. Also recommendation to use same carrier frequency. While polarization can be varied, it was urged that the same polarization (radiation beam toward back of animal and vertical) be used in humans but that absorbent seat and gonadal protection be provided. While posterior presentation is utilized, protection of eyes should be considered.

(S) It was recommended that a medical examination function be established as a separate entity from the research function. Thus, the physical well-being of the subjects would be ascertained and reviewed periodically by medical expertise, which is not directly associated with the purpose of the effort. This medical examining function would not be privy to Pandora but would be given the cover story. It was noted that this separate examination procedure, if properly defined, could provide useful data as well as a safety check for the program. General Hughes thought that such a medical evaluation function could be arranged through the new commander of Walter Reed. In view of the fact that the morphological changes (cytological) which have been found in the CNS of animals exposed to the signal appeared in the visual cortex (as well as other areas), flicker fusion studies should be incorporated into the medical examination. Also, slit lamp and visual field checks should be made and audiograms done. It was also recommended that a separate psychiatric evaluation should be accomplished before and after the study. It was not resolved as to whether there should be separate psychiatric screening in addition to the research program screening procedures. This separate medical function or task force may be referred to as the "medical monitoring task force." It was recommended that a specific chain-of-command be established to be certain that in the changing personnel structure of Walter Reed. the appropriate responsibiilties are established, and thus, the research team will know whom to work through re the medical monitoring function. It was recommended that the medical monitoring procedure include:

Slit lamp examination: initially 90 days, 180 days.
Visual fields examination: initially 90 days, 180 days.
*Audiogram: initially 90 days, 180 days.
ECG: once per week.
**Physician perform general check-up once per week.
*At end of day.
**Have responsibility to be certain that all data are entered on record.

(S) Although the panel expressed some concern that the experiment, as defined by the protocol, might result in findings which would be difficult to characterize as definite indications of effects of the signal on man, i.e., the problems of characterizing changes in each individual and as his own control and of satisfying criteria of group statistics. It was recommended that at least one of the subjects and perhaps two go through the entire procedure except that they not be exposed to the signal. The fact that there are to be two rooms would facilities this approach.

(S) There was also continuing concern expressed regarding the effects of the signal on the measuring system itself, i.e., signal artifacts. The panel recommended continued scrutiny of this problem. The panel requested an up-to-date bibliography of the effects of microwaves on biological systems. It was noted that there is a recent article in the Canadian Journal of Microwaves.

Respectfully submitted by Lysle Peterson, Chairman.

MINUTES OF PANDORA MEETING OF JUNE 18, 1969

Present.—Science Advisory Committee: Dr. Joseph E. Barmack, Dr. James N. Brown[1], Dr. H. Allen Ecker, Dr. Lysle H. Peterson, Chairman, Dr. Herbert Pollack, Dr. Lawrence Sher.[1]

Walter Reed Army Institute of Research: Colonel Joseph V. Brady, Dr. Thomas W. Frazier, Mr. T. Daryl Hawkins, Colonel Merrill C. Johnson, Major James T. McIlwain.

Mr. Richard S. Cesaro, ARPA. Dr. John J. Collins, (CNO), USN. Mr. H. Mark Grove, Wright-Patterson AFB. Mr. Albert Rubenstein, ARPA.

Absent.—Dr. Joseph Kubis, Science Advisory Committee, Dr. Joseph C. Sharp, N.Y. State Dept. of Health, Mr. Harris B. Stone, (CNO), USN.

(S) The minutes of the previous meeting (May 12, 1969) were discussed. Dr. Peterson explained that the questions regarding the WRAIR protocol were stated as those which were raised for discussion at that meeting. The discussion associated with these questions resulted in a general agreement that the protocol in general provided an appropriate initial approach with human subjects. Furthermore, the nature of the problem together with constraints of available time, facilities, personnel and funds, and the scope of the approach result in statistical problems from the use of a small "n." A protocol using significantly more subjects would be more desirable but would delay the program considerably. It was agreed that for the first approach, the small "n" would be acceptable. The primary purpose of this meeting (June 18, 1969) was to consider the approach in more detail and to hear reports from ARPA and WRAIR regarding broad approaches to the solution of the Pandora and related problems:

(S) Mr. Cesaro reminded the Committee of the urgency and high priority which ARPA assigns to the Pandora program; it is important to make major advances in solving the problem in FY 70; the Advisory Committee was invited to give as much attention and creative thinking to the problem as it can. He defined the Advisory Committee's role and that its effectiveness would be enhanced by maintaining a close and continuing association with the Walter Reed group. His view of the overall problem was summarized:

1. Investigative programs should be designed to take major bites at the problem to achieve definite indications of whether or not there are effects on humans of microwaves under conditions simulating, as closely as appropriate, the Moscow signal. Furthermore, he urged that the experimental programs be relevant to the Pandora problem and provide significant results, negative or positive. He reminded the Committee that, conversely, it would be inappropriate to follow paths which while they might be interesting scientifically, would not be relevant to the problem.
2. While there is evidence that low energy (less than 10 mw/cm^2) R.F. radiation does penetrate to the CNS in primates, a significant and relevant question is how the penetration occurs, i.e., the mechanism re microwave characteristic and biomedical engineering principles. Such questions relate to whether or not the Moscow signal is unique and to whether the Soviets have special insight into the effects and use of athermal microwave radiation on man. The WRAIR experience indicates that C. W. has no effect, but modulation does.
3. There appears to be interrelationships of signal time and biological effects, which should be evaluated, i.e., biological on-off effects phased to the on-off character of the signal, i.e., short response times, intermediate and long time effects together with intermittent and long exposures, i.e., at least nine combinations possible.
4. The biomedical effects may include (i) physiological, (ii) behavioral, and (iii) genetic. Each general class re short and long time effects should be evaluated.
5. Man should be emphasized as the object in the investigations both because he is the obvious recipient and because he is in many ways a more effective reporter of effects.
6. Behavioral investigations should include attitudinal (subjective) considerations and measures.

(S) Discussion centered next on details of the WRAIR protocol. There was a consensus among the WRAIR and Committee members that the general approach of the protocol is appropriate and that in the initial stages of the effort, many "on-the-spot" decisions would have to be made because of the uncertainty of aspects of the program. As these uncertainties are clarified, the protocol would become better defined. The areas considered which require initial exploration to provide better definition are:

---

[1] First attendance.

1. Exposure. It was the concensus that the aim should be to duplicate or simulate the Moscow environment as much as appropriate to solve the problem. Since exposure to the Moscow signal tended to be over an eight- to ten-hour period, it is thought that the exposure of subjects to he Special Signal should approximate that time frame. Furthermore, the primate findings were based on a seven-day, ten hours each day, exposure. It is suggested that the protocol indicate exposures up to eight to ten hours each day rather than the one-hour cycle providing four hours total per day.

2. The instrumentation artifact question re possible E. E. G. recordings be explored vigorously. The differences between primate and man with respect to head dimensions, effect of beam incidence, etc., must be reviewed and analyzed.

3. The physiological and medical monitoring include the array noted in the minutes of May 12, the matrix presented by Dr. McIlwain, portable ECG for continuous monitoring and the utilization of *lower-body, negative-pressure* plethysmography (LBNPP). It is recognized that the Soviet literature refers extensively to cardiovascular effects of microwave radiation. The nature of the reported behavior of the cardiovascular system requires relatively continuous monitoring to characterize significant effects from normal variations. Also, it is recognized that LBNPP is an accepted and relatively sensitive measure of cardiovascular "deconditioning" (in the physiological sense). In addition to the special tests, the medical monitor would be responsible for the routine physical examination, regular daily inspection of subjects and to adhere to the responsibilities associated with AR 70–25. These procedures would be worked out through the Office of the Surgeon General. Dept. of the Army, and jointly with WRAIR operational group and relative to security requirements defined by ARPA. ARPA agreed to present in writing, the security requirements for the program.

(S) The Committee recognizes that a period of uncertainty exists in the early phases of developing such a program and that the program director will require a degree of attitude in conducting pilot experiments before finalizing a detailed protocol. The Advisory Committee agreed to work closely with WRAIR in considerations of refinements of the protocol.

(S) The Committee agreed to conduct "brainstorming" sessions relative to the general Pandora problems in the context of ARPA's interests and responsibilities. The Committee expressed a need for more, yet manageable, literature review and information relative to the problem especially re the Soviet literature and from whatever sources useful information could be obtained. It was agreed that Dr. Pollack and Dr. McIlwain would assemble a "package" of useful documents to be distributed to the Committee. There are general discussion about various documents known to the attendees. It was agreed that several documents were relevant and appropriate, e.g., the IDA analysis due out soon, a document by Dr. Robert D. Turner, U.S.A Standards document, the ERMAC report, a report by Castlr and Dodge, one by Castle, one by Thompson, and the Presman summary. It was also agreed that ARPA would make available, to the Committee, any information that is relevant to the problem. It was also agreed that the agenda of the Advisory Committee would automatically include a call for a progress report and new, relevant information from Committee members, WRAIR, and ARPA.

(S) Dr. McIlwain and Data Corporation representatives presented a demonstration of the BEER project and application of a computer-based information storage and retrieval system to provide rapid access to files on microwave related information. It is expected that user needs and responses will soon be tested by ARPA and WRAIR.

(S) A correction of the minutes of May 12 is noted, i.e., that Dr. McIlwain participated as a principal in developing the WRAIR protocol.

(u) The next meeting is scheduled for July 16, 1969.

Respectfully submitted by Lysle Peterson, Chairman.

MINUTES OF PANDORA MEETING OF JULY 16, 1969

Present.—Science Advisory Committee: Dr. Joseph E. Barmack, Dr. James N. Brown, Dr. H. Allen Ecker, Dr. Joseph Kubis, Dr. Lysle H. Peterson, Chairman, Dr. Herbert Pollack, Dr. Lawrence Sher.

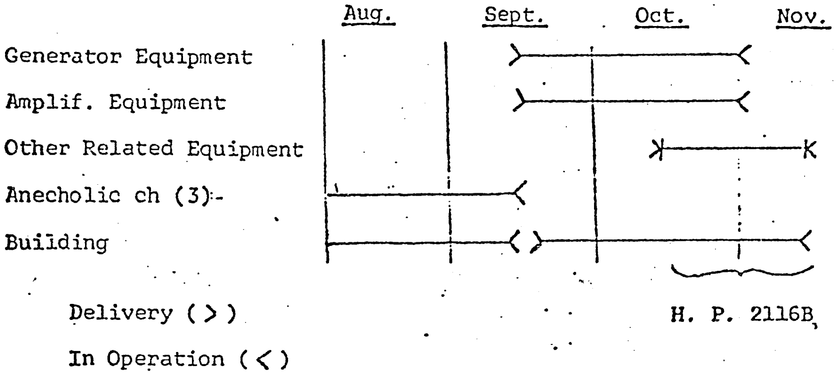
Walter Reed Army Institute of Research: Colonel Joseph V. Brady, Dr. Thomas W. Frazier, Mr. T. Daryl Hawkins, Colonel Merrill C. Johnson, Major James T. McIlwain.

Mr. Richrad S. Cesaro, ARPA; Dr. John J. Collins, (CNO), USN; Mr. H. Mark Grove, Wright-Patterson AFB; Mr. Albert Rubenstein, ARPA; Dr. Stanley Marder[1], IDA; Dr. Joseph C. Sharp, N.Y. State Department. of Health.

Absent: Mr. Harris B. Stone, (CNO), USN.

(S) The meeting was convened at 0930 at Building 503, Forrest Glen Annex, Walter Reed Hospital. The purpose of the meeting at Walter Reed was to review the developments of the facilities and programs re site, to review schedule for completion of the program and to give new Committee members the opportunity to see the laboratories.

(S) Major McIlwain and Mr. Grove led a presentation of schedules to complete the development of the facilities:



(S) Discussion included estimates of signal stability, flexibility, and obsolescence of system. Mr. Grove indicated that satisfactory stability could be expected re 15 ft. cube, that the system was modular and could be expanded, and that range extended from 250 megahertz to 10 gigahertz.

(S) Discussion then focused upon the relevance of the signals to the Moscow signal. It was stressed again that the signal used in the forthcoming experiments should (i) be comparable to previous experiments at the laboratory, (ii) be relevant to the Pandora problem, (iii) the signal characteristics be calibrated periodically as referenced to a standardization technique and (iv) possible signal artifacts (i.e., signals recorded from biomedical transducers due to direct effects of the microwave input in contrast to microwave input effects on the biomedical system) should be elucidated and evaluated.

(S) Discussion also focused upon the software program, i.e., the evaluation of data via computer system. Mr. Grove and Major McIlwain defined three software areas: (i) that developed by Ross Adey at U.C.L.A., (ii) that developed for the internal logic of the equipment to be delivered (H.P. 2116B and related system), and (iii) software needed to extend and interface with (i) and (ii). The U.C.L.A. program had been developed to test an array of statistical parameters re EEG signals on the equipment at U.C.L.A. WRAIR has selected from the total U.C.L.A. program certain aspects which were felt necessary for the WRAIR needs, e.g., auto- and cross-correlation, auto- and cross-power spectra, average transients and certain standard statistical processing. These were packaged into the logic of the equipment being delivered by Hewlett-Packard.

WRAIR felt that there were aspects of the U.C.L.A. programs (e.g., conference functions) that were not needed. To duplicate the U.C.L.A. software program would have been too costly and would require too extensive a hardware package. Thus, the special computer package approach was taken. It was not anticipated that extensive, additional software would be needed but that if so, contracting would be more appropriate than developing extensive in-house programming capability.

---

[1] First attendance.

(S) In summary, the WRAIR presentation concluded that:

1. The facility (at least two chambers operational) would be ready for experimental work by mid-October unless unexpected delays occurred.

2. The signal characteristics would be comparable to previous work and that a calibration procedure would be adopted.

(Note: Discussion indicated that the calibration question related to defining the characteristics to be calibrated rather than to capability to calibrate, i.e., to define spectral and energy characteristics to be measured for calibration and standardization.)

3. With the planned program and facilities, the experimental artifact question could be approached within the inherent uncertainty levels. It is known that EEG experimental artifacts do occur and that the question remains as that in a given experiment how much of the recorded response is artifact, i.e., in levels at different EEG frequencies, to what extent is the living brain required. It is expected that the autospectral analogies will be helpful. A two- or three-month program using monkeys is planned.

(S) The Committee reconvened in executive session after lunch at Room 10K5 in IDA to review the present status of the program in the light of Mr. Cesaro's charge to the Commitee. It was agreed that the Committee would participate in certain working sessions devoted to specific problem areas and, whenever appropriate, do so in subgroups relative to the particular expertise involved, would conduct "brainstorming" sessions relative to the overall Pandora question and the various components of the program, and structure agenda for periodic, approximately monthly, meetings such that orderly progress should occur. Furthermore, contributors to the agenda would be invited as early as possible and notified of the material requested. A list of possible agenda items for the future was developed, and it was expected that this list would be considered appraised by Committee members and an agenda for the next meeting defined on or about August 1. It was agreed that the next meeting would be scheduled for August 12 and 13.

(U) The meeting was adjourned at 1700.

Respectfully submitted by Lysle H. Peterson, Chairman.

DRAFT

MINUTES OF PANDORA MEETINGS OF AUGUST 12 AND 13, 1969 (U)

Present.—Science Advisory Committee: Dr. Joseph E. Barmack, Dr. James N. Brown, Dr. H. Allen Ecker, Dr. Joseph Kubis, Dr. Lyle H. Peterson, Chairman, Dr. Herbert Pollack, Executive Secretary, Dr. Lawrence Sher.

The following attended Aug. 12 only: Mr. T. Daryl Hawkins, WRAIR; Major James T. McIlwain, WRAIR; Mr. Daniel Sullivan, ARPA.[1]

Absent.—Colonel Joseph V. Brady, WRAIR; Mr. Richard S. Cesaro, ARPA; Dr. John J. Collins, (CNO), USN; Dr. Thomas W. Frazier, WRAIR: Mr. H. Mark Grove, Wright-Patterson AFB; Colonel Merrill C. Johnson, WRAIR; Mr. Albert Rubenstein, ARPA; Dr. Joseph C. Sharp, N.Y. State Dept. of Health; Mr. Harris B. Stone, (CNO), USN.

(S) I. The minutes of the July 16 meeting were approved with minor modifications, such as the omission of the fact that the Committee had requested a written summary of the WRAIR program to date and an oral presentation of the basic data.

(S) II. Dr. Peterson reviewed the purpose of the meetings (August 12 and 13) as principally that defined at the previous meeting.

A. To have a detailed, full review presented by WRAIR of the background and findings of the Pandora/WRAIR primate studies from their inception to present. Specifically: (i) A review of the background for the development of the program. (ii) Considerations of the expected sensitivity and relevance of the tests used in the program. (iii) Review all findings from all experiments. (iv) Review current protocol for future program.

---

[1] First attendance.

B. To hear Dr. Ecker's report on the work of his subcommittee, which was asked to look into the hardware systems being developed for future work in the program at WRAIR.

C. To discuss follow-up of Big Boy project. The Committee was then, in the remaining time, available to conduct "brain sessions," as requested by Mr. Cesaro.

(S) III. Major McIlwain presented his analysis and conclusions of the WRAIR/Pandora program. It is noted that although Colonel Joseph Brady, Dr. Joseph Sharp, and Mr. Mark Grove were invited, they were unable to attend this meeting. Also, Messrs. Cesaro and Rubenstein were unable to attend because of conflicting duties; however, they were represented by Mr. Dan Sullivan. The Committee's summary of Major McIlwain's review is as follows:

The experimental approach was defined early in 1966 mainly by Drs. Brady and Sharp with Dr. Sharp being assigned primary, direct responsibility for the operational conduct of the experimental program. The earliest studies were pilot studies. The same signal has been used throughout the study except for varied strength. This signal was selected from the "Moscow signal" tapes by a group representing various agencies. Mr. Mark Grove has had a major responsibility for providing the hardware to generate the selected "special" signal for WRAIR. Primate behavior measures were chosen by WRAIR as the primary indicators of an effect of the special signal. Studies comparing exposed and unexposed behavior were divided into three groups: 1. Reaction times, 2. Detection, and 3. Multiple schedule studies.

1. Reaction Time.—Two types of experiments were performed on two monkeys at 4.6 mw/cm^2: (i) *Shock avoidance* (No. 682) 250 trials/day in midday period and (Animal No. 683) 500 trials/day; both a.m. and p.m. periods.

Results: (a) No significant differences between experimental (exposed) and nonexposed periods, and no significant differences between a.m. and p.m. trials. was exposed to 4.6 mw/cm^2 at 11-second intervals. The second monkey was exposed to 20 mw/cm^2 at 60-second intervals.

Results: No significant detection elicited by either monkey.

Conclusion: The animals showed no response to the microwave signal at least in this regimen.

3. *Multiple Schedule.*—This was regarded as the most critical aspect of the experimental program and involved learning performances for nine sessions on four monkeys, using a progressive, fixed ratio reward (PRL) and alternating with a differential reinforcement of low rates (DRL). Six measures were examined using 4.6 mw/cm^2 as average field strength of the signal: (i) DRL distributions. (ii) Latency of the DRL. (iii) Average number of time-out responses. (iv) Average time per time-out. (v) Average pause time for each ratio step. (vi) Average running time within each ratio step. Of these, the only measure that showed any possible significant effect was the DRL distribution measure, but the data were internally contradictory. A further analysis was made of (i) the number of uninterpreted pauses exceding ten minutes, (ii) work stoppages for any reason, including equipment malfunction, and (iii) total number of pellets earned.

Results: In two of the nine sessions in which the full-power special signal was used, uninterpretable data were obtained either because of equipment malfunction or the use of reinforcement schedules (which reward certain types of stoppages) were recognized as contributing themselves to work stoppages. In two of the nine sessions, there was no effect of the signal; in three (or four) of the nine sessions, there were effects, but they were not cumulative; in one or possibly two sessions, there were unexplained work stoppages which, in the light of the total experience, appear to be random variations found as often in control as in exposed sessions.

Conclusions: There is no convincing evidence of an effect of the special signal on the performance of monkeys.

In addition, Dr. McIlwain acknowledged that the studies had primarily involved behavioral analysis with little effort made to analyze physiological functions, e.g., cardiovascular.

The Committee was told that Dr. McIlwain had not had the opportunity to present his analysis and conclusions to Drs. Sharp and Brady although he had briefly and informally conferred with Dr. Brady. Although the Commitee had not previously had any other detailed analysis of the WRAIR program findings, it was apparent that the conclusions presented earlier by Dr. Sharp were significantly different from those of Dr. McIlwain.

The Committee felt that because of the importance of these differences, the WRAIR program principals, Drs. Brady, Sharp, McIlwain, etc., should attempt to resolve the inconsistencies of their conclusions. The significant differences are, of course, whether or not there are established effects of the special signal on primate behavior as evidenced from the WRAIR program. It was also noted that no technical report had been written regarding the program to date. Dr. McIlwain agreed to furnish the Committee with a written summary of his presentation. The Committee expressed the desire to analyze the raw data themselves.

(S) IV. Dr. H. Allen Ecker presented the findings of his subcommittee on the functions and characteristics of the instrumentation being developed for the expanded WRAIR program. (See minutes of July 16.) A written summary of Dr. Ecker's report is appended (Exhibit A). In discussion, it was concluded that the capacity of the instrumentation exceeds present requirements, but the rational that if the program is expanded and extended, that added requirements will develop, is probably sound.

Discussion regarding the special signal was withheld until after Dr. Ecker's presentation although this major attempt to duplicate it must start from a thorough analysis. To date, the analysis has not, apparently, been thorough; a deficiency in the Pandora effort.

Mr. Daniel Sullivan of ARPA was requested to see whether the signal analysis could be made available to the Committee.

(S) V. A brief review of Big Boy reminded the Committee that the results of the Saratoga study were essentially inconclusive although the testing technology and programs were worked out and proved feasible and reliable with certain suggested improvements. (A report has been written of the Saratoga effort.) A possible reason for the inconclusiveness of the Saratoga study was that the levels of microwave radiation measured at sites where tested personnel were located were found to be extremely low and the exposure time very slight. The Committee recommends that the approach of using established, operational radar stations to test the effects of microwaves on humans be followed-up. Dr. McIlwain indicated that he and Mark Grove had looked at the possibilities of several ground-based establishments, such as those at Monmouth, White Sands, Fort Sill, Hawk missile systems (e.g., El Paso), etc. Their conclusions are that populations of men exposed to radiation are too unstable to be effective for tests. It was also noted that the Navy has at least seven communications * * *

INSTRUMENTATION REVIEW

On 31 July 1969 Dr. James N. Brown, Mr. Mark Grove and Dr. H. Allen Ecker met at Georgia Tech to review the planned instrumentation for the new facility at WRAIR. Since the schedule for completion of equipment was discussed at some length at the last Pandora Panel Meeting and is recorded in the minutes of that meeting, further discussion of the schedule did not appear necessary. The two major items that were reviewed are (1) the Signal Generation Equipment and (2) the Data Recording and Processing Equipment. Neither the variables to be measured, the method of their measurement nor software requirements was discussed.

Data recording and processing equipment

A simplified block diagram of the Data Recording and Processing Equipment for the new facility is shown in Figure 1. Hewlett-Packard is the prime contractor for design and installation of this system and a very flexible and well-coordinated system which offers excellent data analysis capability has been designed. The use of pre-programmed analyzers such as the new Hewlett-Packard 5450 Fourier Analyzer provides pre-programmed analysis techniques and therefore, reduces the initial software requirements. Both analog and digital data storage equipment is included. Care has been taken to provide calibration and monitoring capability throughout the system. Since the variables to be measured and analyzed were not defined at the time of equipment design, it appears that the money available for this instrumentation was used wisely to provide a very flexible data recording and processing system.

A suggestion for increased capability is the use of a Honeywell Visicorder in place of the currently planned HP 7878 Ink Oscillograph. The visicorder offers a bandwidth of 5 KHz with an extension to 10 KHz with reduced amplitude; whereas the HP Ink Recorder has a maximum bandwidth of 150 Hz. In any system in which input variables are unknown, bandwidth can be a limiting factor on flexibility of the processing system.

Signal generation equipment

The task of designating the system to generate the desired RF signal was accomplished in house with Litton Industries providing the special high voltage power supply. A preliminary block diagram of the basic components of the system is shown in Figure 2. The basic RF oscillator is an HP 8690 Sweep Oscillator. The frequency modulation signal is generated by summing the output from two Hewlett-Packard 3300 Function Generators and a General Radio 1390 Noise Generator; current plans do not call for amplitude modulation. However, a PIN modulator could be inserted between the basic oscillator and the first amplifier as indicated by X on the block diagram. A PIN modulator is an easy and flexible way to provide amplitude modulation with minimum interaction with the desired frequency modulation.

A two stage drive section in the form of sequential 1 watt and 10 watt TWT amplifiers is part of the present design. TWT's with 30 dB gain are common; therefore, in a conventional system, drivers separated by only 10 dB in output would not be an efficient system; the desire for extreme linearity prompted the choice of this configuration.

Provisions are made to monitor the power level and the frequency spectrum after the 10 watt TWT. The results of this monitoring will be available to the Data Processing System.

The present plans call for Klystrons to amplify the signal to a 1-to-12 kilowatt level. An amplifier of this type in the frequency range of interest would have only approximately 5 MHz bandwidth with 40 dB of gain. Since only about 23 dB of gain would be required to produce 2 kilowatts from a 10 watt drive, it would be possible to stagger tune the Klystron amplifier sections and increase the bandwidth at the expense of gain; perhaps as much as 15 or 20 MHz bandwidths could be achieved. A major design item in the Signal Generation System is the high voltage power supply and associated protective circuitry for the Klystron amplifier. At present, a 10 kilowatt-1 amp power supply is being designed.

After the Klystron amplifier, monitoring of the output power will be provided as well as isolation from undesired or reflected signals. The transmitting antenna will be a Scientific Atlanta Standard Gain Horn with approximately 18 dB gain. The three dB beamwidths in the E and H planes are 23° and 22° respectively. A probe antenna and associated thermistor mount and power meter are provided down range for monitoring power levels at that point.

The signal generation system as proposed provides a flexible source for a frequency and amplitude modulated RF signal with the exception of the final Klystron amplifier. Octave bandwidths are common practice in TWT amplifiers whereas Klystrons usually exhibit less than a one percent bandwidth. If one is assured that the signal to be simulated will never exceed the bandwidth limitation of the Klystron amplifier, then the proposed system will be adequate. However, if the possibility of a larger bandwidth requirement exists, the search for broader bandwidth and perhaps higher powered output tubes should be made. Both Hughes and Varian advertise 1 KW CW TWT amplifiers in the frequency range of interest. A recent advertisement by Varian in the March 1969 Microwave Journal indicates that 10 KW CW TWT's have been built and delivered. Also, recent developments in CW cross field amplifiers could provide a very efficient and reasonably broadband final transmitter stage. Both Ratheon and SFD have made significant advances in the development of cross field amplifiers. It should be emphasized that the system was originally conceived before the above tubes were catalog items. Also, cost and scheduling can be limiting factors.

The choice of a standard gain horn for the transmitting antenna provides a simple method of coupling to free space. However, the far-field criterion must be satisfied to establish a uniform plane wave over a region in space. If a larger area and a more uniform wave is desired, a large collimating reflector type antenna could be substituted for the standard gain horn. Of course, a large reflector antenna would be much more expensive.

Concluding remarks

The results of the review of instrumentation indicate that at this point both the Data Recording and Processing System and the Signal Generation System have been well planned. However, two pressing issues must be resolved. (1) It is imperative that rapid decisions be made on the variables to be measured and on the desired methods of analyses to permit determination of required software. (2) A more thorough analysis of the RF signal to be simulated is necessary. The bandwidth requirements of the output amplifier hinge on the results of that analysis.

Respectfully submitted,

H. ALLEN ECKER.

ON THE EVALUATION OF DATA ASSOCIATED WITH PANDORA

Preliminary Report by Joseph A. Kubis 12/4/69

SECTION 1: INTRODUCTION

Found

In a letter dated October 29, 1969, Dr. Lysle H. Peterson invited me to help in "developing criteria for the evaluation of data associated with Pandora." I agreed to talk with the project investigators, examine whatever records were available, and prepare a report of my findings and recommendations.

My purpose in meeting with those intimately connected with the project was to solicit ideas on how they felt the data should be evaluated. The examination of basic and derived data was not only to gain an understanding of the analyses already made but also to recommend additional procedures the structure of the data might suggest.

Finally, I suggested that whatever findings and recommendations I would make be reviewed by Dr. Peterson, who with the assistance of Dr. Pollack, would decide whether further effort on my part would be desirable.

Problem

The underlying problem which led to this report was the existence of two different approaches to the analysis of Pandora data—one by Dr. J. Sharp, the other by Maj. J. McIlwain. In Dr. Sharp's view, although most of the experiments produced negative results, certain aspects of the data (IRT changes and work stoppages) are suggestive of an exposure effect due to the WRAIR signal. Admitting that some changes in the animal's behavior could not be explained by artifacts, Maj. McIlwain believes that there is insufficient consistency in the data to seriously entertain the notion of an exposure effect due to the special WRAIR signal.

The evidence adduced by Dr. Sharp was a series of graphs and a cataloguing of the instances of work stoppages attributed to the special signal. Maj. McIlwain's position is that there are clerical errors in one of the graphs and that the sequence showing a shift in the IRT distribution is a function of the days selected for graphing. He has presented graphs from baseline periods that are similar to the graphs in the IRT sequence. As for work stoppages, Maj. McIlwain noted that a number of them could be associated with mechanical and other failures. Acknowledging that such difficulties limit interpretations, Dr. Sharp believes that there are some runs that are artifact-free and that these should undergo intensive analysis.

Appointments were made with the following individuals associated with Pandora: Col. J. Brady, Col. E. Buescher, Mr. R. Cesaro, Maj. J. McIwain, Col. W. Meroncy, Mr. A. Rubenstein, Dr. J. Sharp.

During these visits a number of reports were examined as well as the basic and derived data from the experiments. A description of the visits made and the materials examined may be found in Appendixes A and D.

SECTION 2: COMPONENTS OF THE PROBLEM

As stated in Section 1, the problem seems simple enough. However, it is embedded in a mosaic of components, which, if clearly understood, will place the problem in proper perspective.

Project as a whole

Essential to a proper evaluation of the problem is the consideration of how the project as a whole was viewed. Dr. Sharp interpreted his task as exploratory in nature—a series of pilot experiments to search for leads that might prove fruitful in a more extended research effort. An examination of the experiment protocols does support this interpretation: many experiments were tried, many conditions were tested, and many changes in procedure were introduced during the experimental program.

The inevitable outcome of a pilot program is an accumulation of a wide diversity of data, fractionated into blocks obtained under various combinations of conditions. Experimental outcomes, uncontaminated by changes in condition or possible influence of several factors, are hard to come by. A particularly pertinent example from the Pandora experiments may be found in Appendix C.

A second consequence of a pilot program is that conclusions cannot be asserted with great confidence because of the limited number of observations that are available. Statistical tests performed on even promising segments of data might very well lead to insignificant results because the sample size is small.

From the nature of the case, then, the conclusions generated from the Pandora experiments at WRAIR must be considered as tentative and suggestive except for segments of data sufficiently numerous and free from the contaminating effects of changes in condition or intrusion of uncontrolled factors.

The WRAIR experimental program contains an imaginative complex of procedures which tap various behavioral functions that are uniquely packaged into a well-motivated work day for the monkey. A description of the various "jobs" comprising the monkey's work day may be found in Appendix B.

As structured at present, the experimental program generates data from the same monkey exposed to a variety of conditions. At times he is exposed to a variety of conditions. At times he is exposed to a signal, at times not. Each monkey is his own control. This is an efficient design provided that a minimally varying baseline can be achieved, that the baseline is stable over relatively long periods of time, that the behavior observed is sensitive to the experimental "intrusion," and that strict control over most of the confounding conditions can be maintained throughout the experiment. When these conditions cannot be easily met, the design can benefit appreciably from the inclusion of control subjects.

From an interpretative point of view, it is felt that the results of the Pandora experiments would have been more discriminative with the addition of control animals. In particular, it would have been desirable to control for the effects of "isolation" and "confinement." Over a long period of time, say several months, it is possible that continued isolation and confinement could bring about an erratic temporal pattern in the monkey's performance.

One further point about procedure. The complexity of the present task routine makes inevitable a long turn-around-time for a single animal. He requires a long training period and is subjected for a long time to a stimulus whose measurable effect may be long delayed. Inevitably this means that the experiment is based on a small sample with an effect that may be weak or ephemeral. In turn, this leads either to very limited generalizeability or to inconclusive statistical results. At worst, it could lead to accepting as significant results that reflect long-range and unknown fluctuations in the animal's condition in no way related to the experimental signal. Expanded facilities, of course, would help since more experimental and more control animals could be used. In addition, the use of tasks or animals with a shorter turn-around-time should also be considered.

Flaws in test conditions and baseline

As mentioned earlier, test conditions were changed relatively frequently. Some changes were due to limitations of test facilities, for example, having the animal tested or trained in the "ice box" and then tested in the anechoic chamber. In other cases, changes were introduced to determine if a facilitating or debilitating effect would ensue, as, for example, changing the character or strength of signal exposure. In any event, the greater the number of changes in conditions (especially if used in combination), the smaller the chances that an adequate baseline would be obtained to test for the specific effect under consideration.

As illustrated in Appendix C, the animal was exposed to a number of differing conditions in various combinations within a relatively short period of time. These were: night vs. day work, alone vs. with another animal, "ice box" vs. anechoic chamber. WRAIR signal on vs. WRAIR signal off, new chair, new lever, new speaker vs. old chair, old lever, old speaker. Good baselines for testing the effects of all these changes might prove impossible of attainment.

Adequacy of baseline is a serious but not hopeless problem in the WRAIR experiments. The basic shortcoming is that the number of observations for the appropriate baseline may be small.

Functioning system

The usual mechanical difficulties were experienced during the course of the Pandora experiments: feeder jam, empty feeder, ink failure, etc. Power fluctuations and circuit malfunction also occurred.

One of the obvious results of such malfunction is loss of data. The problem, however, is more complicated. It is very likely that the finely trained animal may have had his habit patterns disturbed because of the inappropriate cues or inadequate food rewards. His "confusion" and altered motivation may have affected his behavior for the remainder of the day and possibly for a day or more after the malfunction. The fundamental questions are: Subsequent to the identified malfunction, how much data should be discarded as unreliable? How reliable is the data immediately before the difficulty was identified?

Relevant criteria for these situations may have been developed by the laboratory in the course of its experience. In any event, an informed opinion to corroborate the adequacy of such criteria should be obtained from an outstanding expert in the field of animal experimentation. It is suggested that such information be obtained from Col. J. Brady.

Analytic procedures, etc.

Interpretation of data is strongly connected to the model assumed to underly the data. Similarly, the model will tend to determine the character and direction of the statistical procedures one would employ to analyze the data. As a simple example, the model may specify that the exposure signal enhances the functioning of the organism, or that it causes a deterioration in its functioning, or that it enhances some functions and brings about a deterioration in others, or that it has no observable effect at all.

The analysis and interpretation of the Pandora experiments will depend, then, on the characteristics of the model one considers appropriate for the data. For example: Is the effect cumulative (or non-cumulative)? Is the effect reversible (or irreversible)? Is the effect ephemeral, so that it is generally observable only under direct exposure?

One must take into account that the level of significance for the statistical tests is no longer the conventional one agreed upon. In a similar vein, as one tests more and more relatively independent variables within the same experiment, one is likely to obtain some results that seem to point to a statistically significant effect when, in reality, there is none. This is analogous to the traditional urn problem (containing, for example, 95 white and 5 red balls) in which the probability of picking a red ball in one draw is .05. Yet the probability of obtaining a red ball increases rapidly as I make many successive draws from the urn (replacement model).

The Pandora experiments reflect a multivariate model embedded in a time series. Although the multivariate time series model is not recommended for the present set of Pandora experiments, some thought might be given to its use when a critical and definitive set of experiments is decided upon.

SECTION 3: RECOMMENDATIONS

Basic issues

Work stoppage.—A relevant scale needs to be developed for the application of this concept. In Maj. McIlwain's analyses an animal who "stopped work and did not recommence within ten minutes of the end of the day" is said to have engaged in a work stoppage. As used in a nominal-scale situation, a work stoppage of 11 minutes is equivalent to one of several hours.

It is recommended that the distribution of the lengths of work stoppages be compiled so that the parameters of the distribution can be estimated. This should help in establishing a weighting procedure which would give more weight to longer than to shorter work stoppages. (Often in the case of time variables, a logarithmic transformation provides an adequate solution.)

Distribution shift.—In his presentation of a series of overlays (exposure data) compared to a distribution of baseline data, Dr. Sharp can be challenged concerning the criterion he used to select his time points. If this criterion had no theoretical jurisdiction, then distributions at other time points could have been taken just as well. What Dr. Sharp wanted to show is a global trend of the distributions without the necessity of processing all the data. Maj. McIlwain's "counter examples" taken from baseline data, though pictorially effective, may suffer from a similar selection bias.

Two analytic approaches seem to be feasible: (1) studying the change in the distribution as a whole over time; (2) utilizing several appropriate parameters of the distributions and studying their trend over time.

A first approach towards evaluating the change in the distribution as a whole over time might consider fractionating a time period into successive segments and then constructing an "average" distribution for each segment. The differences between distributions could be tested by a Kolmogorov-Smirnov type of statistic. This test procedure could be improved by the development of a Studentized range type of statistic for total distributions analogous * * *

In the second approach mentioned above, several basic parameters would be estimated for each distribution at each time point. The median and interquartile range would be appropriate. The distribution of these statistics over time would be available for analysis. Often enough, the hypothesis under test is relatively simple, as, for example, that the median (or interquartile range) increases over time. Curve fitting procedures could be used to test this or more complex functions. Orthogonal polynomials also could be utilized in testing for trend.

Either of the two approaches should be used. Of these, the trend analysis would seem more feasible, at least initially. The statistics (median and interquartile range) are available and the test procedure is characterized by ease of computation and interpretation.

Baseline problems

From an examination of the data and the graphs based on the data, it would be a questionable procedure to use many of the original baselines to evaluate the effects of the WRAIR signal. For example, the baseline developed in the "icebox" is not relevant to test for the effect of the signal in the anechoic chamber. Similarly, a baseline developed on a night "shift" cannot be used to test the effects of the WRAIR signal given during the day. Discouraged by the problem of an adequate baseline, Maj McIlwain has refrained from using baselines in his analyses of the exposure periods.

It is recommended that the initial period of orientation to any change in condition be considered as a source for baseline data. For example, after transfer from the "icebox" to the anechoic chamber, the animal is usually tested for a number of days without exposure to the WRAIR signal. A portion of this adaptation period, once the perturbations settle down, could be used as the base against which the effects of the signal should be evaluated. Despite the fewer number of points available, they should be used as baseline data for the particular comparison under consideration.

The issue pointed up in this discussion is that there is no general baseline for all combinations of test situations. Changes in test situations seem to produce more pronounced effects than exposure stimuli.

Division of exposure period

In the extant analyses, Maj. McIlwain has divided the exposure period into two equal segments. He has reasoned that if the effect is cumulative, the average value of the two segments should differ—the greater effect being observed in the second half of the exposure period. This analysis loses some valuable information. In the first place it gives no information about the comparison of the exposure period with the * * *

It is recommended that the exposure period be divided into more than two segments. In particular, since it is anticipated that the new baseline periods will not contain many points (confer discussion in the previous section), it would be advantageous to divide the exposure period into segments equal in size to the baseline period. The analyses, nonparametric analogues of analysis of variance, will have the following advantages: (1) a comparison with baseline data will be available, and (2) a trend would be more discernible and easily tested.

Typical considerations

Where hypothesis are specific and directional, one-tailed tests should be used. The possibility of an enhancement effect on some functions under exposure should not be discounted. Two-tailed tests in these situations would leave the issue open ended.

It is recommended that the personnel at WRAIR continue using nonparametric statistics wherever feasible. These are the statistics of choice since the distributions of many of the statistics used in behavioral measurements have no known parametric representation. Further, they have good efficiency and they are simply and easily calculated.

It is also recommended that these calculations be done by clerical personnel trained and supervised by Maj. McIlwain.

It is urged that the operational definitions of relevant concepts (ex. pause), the specification of models, evaluation of effects of malfunction, rejection of inadequate data, and other such problems be discussed with the expertise available in-house at WRAIR. In particular, the services of Col. J. Brady should be secured, since he is an outstanding authority in behavioral matters, especially those pertaining to animal behavior.

STATE OF ALABAMA,
DEPARTMENT OF PUBLIC HEALTH,
Montgomery, Ala., June 15, 1977.

U.S. SENATE,
Committee on Commerce, Science, and Transportation,
U.S. Capitol, Washington, D.C.

GENTLEMEN: This letter is in response to your questions at the Conference of Radiation Control Program Directors as part of their testimony to be given on June 29, 1977.

(I) We have reviewed the program and conclude that there are several areas which need resolutions or are of concern to the consuming public. Some of these issues may not require legislation but either changes in regulations or an approporiate policy decision. These areas are as follows:

(*a*) *Radium and Other Non-Agreement Radioactive Materials.*—As the Committee is aware, all source material, special nuclear material, and byproduct materials are covered by the Atomic Energy Act of 1954, as amended. Regulatory control of these materials is currently vested in the U.S. Nuclear Regulatory Commission or by special agreement in Agreement States. There are other radioactive materials such as radium which are not presently regulated by any federal agency; however, most, if not all, of the Agreement States regulate these materials similarly to source, special nuclear, and byproduct materials. The fact that some twenty (20) states do not license the users of these non-agreement radioactive materials is a gap in their control. Each Agreement State can cite several instances where these non-agreement materials have been transferred to unlicensed users from Non-Agreement States. In some cases the equipment being transferred did not meet minimal standards or give any indication that it contained radioactive material. Currently the Bureau of Radiological Health of the BDA has a voluntary program to identify equipment containing these materials. While this is an improvement over the situation that existed several years ago, we still are having materials distributed to non-licensees, improperly labeled, or with other questionable manufacturing practices.

We suggest that the Atomic Energy Act be amended to include these products so that they are regulated like byproduct, source, and special nuclear material. As an alternative, you may wish to amend the Radiation Safety Act of 1968.

(b) *OSHA.*—The Occupational Safety and Health Administration has comprehensive regulations for all health results in the work environment. It has been our experience with OSHA that, in general, they do not have sufficient trained personnel to adequately protect the worker from ionizing radiation. Indeed, virtually every state is doing as many inspections for ionizing radiation alone as OSHA is doing for all other safety and health matters. In addition, most states have specifically trained personnel to do their ionizing radiation inspections. For example, in Alabama everyone inspecting radioactive materials has a Masters Degree. Those inspecting x-ray equipment are registered x-ray technologists and have an additional month and a half specialized radiation training plus three (3) months on the job training.

Presently OSHA's regulations do not totally recognize good health physics practices. Further, in attempting to work with OSHA, they are totally against any state applying to control a single standard such as ionizing radiation. They would accept an application to control a group of standards but not a single standard. In view of the limited resources of individuals trained in the regulation of ionizing radiation as well as the recognition that most states have an ongoing program in ionizing radiation, it would be well for the Committee to consider designating one agency for all regulatory items involving ionizing radiation: and such an agency should utilize to the greatest possible state capabilities similarly to the NRC Agreement State program. As a philosophical point, it would probably be wise to have a different Agency establishing radiation exposure standards.

(c) *Disaster Planning.*—This area of radiation operation has been subject to much public comment, most of which does not leave a true impression of the state of emergency planning. In general most communities can take the necessary protective actions on a timely basis from any hazardous threat normally encountered at peace time; however, that is not to say that improvements should not be made. It has been our experience that the local and state governments are prepared and will take the necessary actions of clear lines of communications and authority are established between the various concerned agencies.

Current federal efforts leave us with several basic impressions:

(1) All emergency planning must take the form of a quasi-military operation or is merely a modification of the nuclear warfare concept. We do not agree that a community will be totally unable to get advice and technical support during a radiation emergency as would occur during a nuclear war. This subtle but significant difference does not appear to be recognized by all federal agencies.

(2) There is a lack of definition of what accident criteria state and local plans should be capable of coping with. Expressed another way no one has told the state and local agencies what accidents have sufficient probability to the expenditure of public mones to design a radiation emergency plan. As an example, everyone knows that it is possible for a 747 to crash into a Super Bowl game with resulting large numbers of fatalities and injuries. We are unaware of anyone who thinks this probability is sufficient to develop a detailed disaster plan for this occurrence. The State of Alabama has since 1971 endeavored to obtain a statement from the federal agencies as to what accident conditions for which we should write a detailed radiation emergency plan. As of this date, such information has not been provided. We understand that it will be provided in the near future.

Because of this lack of accident definition, the State of Alabama and other states have recommended against participating in the NRC's concurrence program for radiation emergency plans for fixed facilities. It does not seem logical or even possible for one to write an emergency plan when the scope of the accident is different for each agency who reviews the plan; however, once there is a general agreement on the accident or accidents for which radiation emergency plans should be prepared, then we believe we can support the NRC's Concurrence Program.

Current guides prepared by the federal agencies are open to interpretation and indeed is contradictory. For example, current NRC regulations define an accident which is used to evaluate the suitability of a specific site; yet, when one takes their emergency planning document, "Guide and Checklist for Development and Evaluation of State and Local Government Radiological Emergency Response Plans in Support of Fixed Nuclear Facilities", NUREG 75/111, one finds under L3 that one is required to have maps showing the physical location of all public, private, and military hospitals or other emergency medical service facilities within the state considered capable of providing medical support for any off-site victims of a radiological incident. Further, these facilities are expected to have trained personnel to care for victims of radiological accidents. At first glance there seems to be no problem until you try to get a decision about the injuries these medical facilities will be treating. Are we to expect several hundred individuals suffering from the radiation syndrome, or are we talking about those people who may be involved in car accidents, etc., during an evacuation? If it is the former, then it is inconsistent with the NRC regulations for design based accidents (DBA), which would not require medical attention. If it is the latter, experience with evacuations shows that you will not need a map of all the medical facilities in the state, nor will you have seen unusual medical problems to require experts to be imported from all over the state. This is just one example of many in which federal agency guidance is inconsistent and confusing.

Regretfully, many federal people envision a situation in which the local community will be unable to get timely technical advice during a radiological emergency. Using this concept, many have proposed using nuclear warfare instrumentation to attempt to evaluate the radiological situation. Indeed they point with pride at how many millions of instruments have been distributed and how many have been trained in their use. Unfortunately they forget that much of the training occurred over ten (10) years ago and that it was oriented to strictly wartime conditions. Further, they conveniently forget that the instruments were designed for particulate fallout and not for gaseous releases which are the most likely releases from nuclear powerplants. One should be aware that many police and fire departments have been given updated training with these instruments, and indeed our own Division has supplemented the training in some cases. I would not suggest that anyone should ignore the availablity of instrumentation that is available or the fact that some people are quite competent in its use. I would suggest to the federal government that rather than trying to have everybody utilize this equipment, a selective approach is desirable both for the choice of the operator of the instrument and the accidents it is used for.

I would specifically suggest that for nuclear powerplants, rather than attempting to train large number of local monitors to make the necessary conversion for civil defense instrument readings, we should insist that the nuclear power plants have adequate staffing and instrumentation to make the initial (four (4) hours) environmental assessments. Most people agree that the initial decisions for protective actions have to be made based on information supplied from the facility. Further, we believe we can get people from the facility to make the necessary environmental measurements quicker and more accurately than we could get a policeman or fireman into the area to get his readings, then make the necessary correction, and hope that he has not forgotten his training. In fact, quite possibly we will have our policemen and firefighting forces engaged in protective actions activities which may be much more important than trying to teach them to read an instrument once every six (6) months. Further, because of instrumentation limitations, the more likely accidents, i.e., those involving milk and food supplies, will not be detected and may lead to initial reports that there is no problem when in fact a significant health problem exists. With radiation accidents, as with accidents involving hazardous chemicals, you do not need a volume of data to determine when and where you need to take a protective action. If we did, many more people would have already been killed by the many chemical accidents we have had in our country.

(II) Alabama continues to support the following resolutions of the Conference:

Year:	*Resolution No.*
1971	1–5
1972	2
1973	1
1974	None
1975	1
1976	1–2
August 1976	1–2

(III) Most of the reasons for calling for more federalization of radiation safety control are given in Number I. We feel that basically one agency should be responsible for all radioactive materials. This would include the licensing of the users, equipment, and the environmental discharges. Further, we feel either the same agency or a different agency should be responsible for the use of ionizing radiation use in the machines. This regulatory control over machine produced radiation would probably be best applied at the manufacturer in the case of the federal government and the user in the case of the state government. In either case provisions should be made for a state to fully participate in the program as a compliance unit. To do otherwise would result in a needless waste of trained resources. This is one of our prime objections to the current OSHA policy.

Currently when we report problems involving machine-produced ionizing radiation, it appears to get swallowed up in the great federal bureaucracy. Perhaps months later, we receive a telegram informing us that at long last a compliance program has been initiated which may last for years. In most cases the state is left powerless to encourage prompter compliance or even know what the details of the compliance program are. We suggest that all of this secrecy is really not necessary and that the states can and should be kept aware of compliance activities regarding this equipment. In many cases states will assist in identifying units remaining in noncompliance, and in most cases have been the initiators of noncompliance activities involving *ionizing* radiation.

One of the major dfficulties of any program is funding. The ability of a state to fund a radiological health program varies widely. We do not claim that all of the problems associated with state radiological health programs are funding related, however, a large number are. Generally those states which are Agreement States are better funded than Non-Agreement States. To encourage states to become Agreement States as well as to support those Agreement States currently in existence, we would suggest that legislation should be considered by Congress which would authorize and require a state to collect license fees for byproduct, source, and special nuclear licenses issued by that state as an agreement State. Such fees would be the same as those charged by the U.S. Nuclear Regulatory Commission and are considered a federal grant to the Agreement State for radiation health and safety purposes. Specifically the federal legislation should authorize the Agreement States to collect and use the fees. This would also equalize the economic disadvantage that currently exists for some operations in Non-Agreement States.

If you have any questions or wish to discuss these matters further, please contact me.

Sincerely,

AUBREY V. GODWIN,
Director, Division of Radiological Health.

COMMENTS SUBMITTED BY UNITED ACTION FOR ANIMALS, INC.

United Action for Animals, Inc. (UAA) submits these comments for inclusion in the record of the Committee's study of the biological effects of radiation. UAA is a membership organization committed to ending unneeded live animal experimentation because UAA believes that live animal experimentation is not a proper or effective way of determining health and safety standards for human beings.

As the testimony before this Committee has indicated, the public is interested in the biological effects of ionizing and non-ionizing radiation in the doses that occur in real life. Except in isolated instances, these are low-dose, chronic exposures. Yet radiation researchers continue to rely on the bombardment of animals, usually with high doses over a short term. The record of this Committee confirms that this method yields little if any information about the biological consequences of the "real life" problem.[1] The only certain product of most present radiation research is injury to thousands and thousands of animals who experience indescribable agony in the process.

In November 1975 Rep. George E. Brown, Jr., held week-long hearings on "The Costs and Effects of Chronic Exposure to Low-Level Pollutants in the Environment," including radiation. At that time, radiation research experts admitted that the cause of death in short-term high-dose radiation experiments "may not be the same" as in real-life low-dose chronic exposures. But only one witness urged the study of chronic doses relevant to the real world. Another witness expressed caution about trying to extrapolate from high to low dose, stating flatly that "we may never know the risk" from chronic low-dose exposure. But there was no consensus on the question of what is a reliable means for determining the radiation risk to humans in everyday situations.

It was the same story in hearings held a year later, in November 1976, by the House Committee on Interior and Insular Affairs, Chairman James A. Haley. There, two more witnesses testified that the biological effects of radiation at high doses are different from those resulting from reallife low-dose exposure levels. (Some scientists point out that high doses of anything overwhelm the body's metabolic pathways, rendering abnormal results.) Again, in these hearings, there was such scientific confusion about the biological effects of low-dose radiation that Dr. Roger Mattson of the Nuclear Regulatory Commission, asked, apparently in frustration: "How do we come to a consensus of scientific opinion of how to protect people from low levels of radiation?"

This, in spite of the fact that radiation research has been going on since the turn of the century.[2] Is it too much to suggest that continued use of live animals in experiments using old shop-worn techniques will not produce the breakthroughs so necessary to understanding the health problems of radiation?

Today's researchers, probably as a result of their education and training in animal research, downgrade the use of other research and testing methods, such as living cells, including human cells, growing and functioning in tissue culture.

---

[1] See, e.g., testimony of Dr. Steven O. Schiff, June 16, p. 5; Dr. Erwin D. J. Bross, June 17, pp. 1–2.

[2] A review published in The Archives of Pathology (34:562) in 1942 on the biological effects of radiation on many species of animals cited references going back to 1903.

Yet in 1965, radiation experts, under sponsorship of the Atomic Energy Commission, published a book entitled "Mammalian Radiation Lethality," in which they described the use of tissue culture in radiation research as follows:

"Quantitative cellular radiobiology was advanced markedly by the introduction of single cell tissue culture techniques which allowed characterization of the radiation response of populations of mammalian cells, as well as individual cells in that population. Introduction of the technique allowed the demonstration, contrary to previous thought, that mammalian cells in tissue culture are comparable in their radiosensitivity to cells irradiated in the live animal. The method is unique in that an inoculum of growing tissue culture cells can be plated out on petri dishes; and if the dilution is sufficiently great, the overwhelming majority of visible colonies that appear in a matter of days will have been derived from, and therefore represent, the original single cells. Thus, following irradiation, the fate of an individual cell and its progeny can be determined accurately by counts of grossly visible colonies." (Mammalian Radiation Lethality, Academic Press, 1965.)

Animal researchers of course know that quantitative (numerically measurable) tissue culture methods exist, but apparently prefer the trial and error of the live animal experiments which are familiar to them. For example, at Rep. Brown's hearings in 1975, a researcher from Oak Ridge (ERDA) first stated:

"If we talk about dose levels where the probability of an effect is one in a thousand or one in a hundred thousand we simply cannot obtain the information from animal experiments for technical, logistical and economic reasons. The very low dose end of the curve, then, cannot be established by empirical observations."

Then he testified:

"It is possible to maintain and grow animal and human tissue cells outside the body in much the manner that bacteria can be grown in dishes of culture media. We know that certain carcinogens (cancer causing agents) can alter the characteristics of these cells so that when they proliferate to form colonies of cells the altered or "transformed" cells form colonies with characteristics that are different from untransformed cells. Furthermore, in some cases at least, these untransformed cells will produce tumors when inoculated into suitable test animals.[3] It would be possible, though technically difficult and tedious, to try to determine if a very small dose of carcinogen caused transformation in one cell in a hundred thousand or perhaps one cell in a million. In theory, at least, dose-response curves could be obtained down to very low levels of effect. The difficulty is that at present we do not know whether this system bears any relationship to what happens in the intact animal. . . . Theories must be consistent with observations at high dose levels."

Thus, despite the inadequacy of the old methods, he is right back where he started: the administration of high doses to animals without a hope of finding any answers.

Although animal researchers profess not to know what the production of cancer in tissue culture "means in animals," the animal of concern in environmental cancer is man. Human cells, obtainable commercially or from hospital surgical services, can be kept viable and functioning in vitro as per the method described by the Oak Ridge researcher. Both radiation and environmental chemicals can be tested on these living cells. The level of radiation (or concentration of environmental chemicals, such as pesticides) that "transforms" normal human cells into cancerous ones can be determined through the use of these living cells. But it only confounds these results to inject the cancerous human cells into foreign hosts—animals (in the 90-year old method that is still being used). Results in tissue culture can be seen within days instead of years, as in the case of live animals. That the method may be "to technical" or tedious"—especially for those trained in animal research—elevates form over substance by giving priority to the experiments and experimenters rather than the knowledge that is being sought.

A Dutch scientist has forcefully summarized the advantages of in vitro research methods:

"At present, only a few investigators use in vitro methods to study X-ray induced transformation [i.e., of normal cells to cancer]. This is unfortunate, because cell culture systems can be used to investigate malignant transformation directly at the cellular level with the exclusion of the interfering factors operating in whole animals.

---

[3] [This is a 90-year old method. Editor's note].

"With these in vitro methods, it is possible to establish dose-response relationships for malignant transformations induced by single and split doses of X-rays and also for other types of radiation. This offers the possibility of obtaining better insight into the potentially carcinogenic effect of very low doses of radiation.

"Another important advantage of in vitro systems is that chemical and viral carcinogens can be introduced and investigated in the same system. This makes these systems suitable for the exploration of the fundamental mechanism of carcinogenesis." (Biology of Radiation Carcinogenesis, p. 301, Raven Press, N.Y., 1976.)

Additionally, there are numerous other modern research methods that are not being used. For example, scientists at Oak Ridge National Laboratory developed a mathematical model for the distribution and excretion of the radioactive element thorium (^{228}TH) and its decay product (^{224}Ra) and used the model to estimate the radiation doses to human organs and tissues from a single intake of thorium. Their model was based on data on humans and dogs reported in the experimental literature. Further, they were able to calculate radium retention in man over a 50-year period of time. (Bull. Math. Biol. 35:129, 1973). By contrast, institutions across the country are still gassing animals (mostly Beagle dogs) with radioactive materials such as plutonium to study the distribution of "hot particles" in the respiratory system.

Probably the most important advance of this century was recently reported. Researchers at private laboratories, under contract with the Environmental Protection Agency, developed a "mathematical prediction system for determining the toxicity of chemical compounds." Their method, based on "sophisticated statistical techniques," permits the predictions of toxicity of untested chemical compounds, now routinely determined in the so-called rat LD50 test (the lethal dose from which 50 percent of the animals must die). Their mathematical prediction system "could also be applied to . . . long-term tests, carcinogenicity, etc. in other species and for other routes of administration." [4]

With proper motivation and incentive, similar or related methods could—and should—be extended to radiation research; there is more than 70 years' data in the published literature to start with.

But only Congress can lead the way to the development of modern, sophisticated research methods in radiation research. We urge that the Committee recommend and prepare legislation to accomplish the following: the elimination of experiments that use old, well worn techniques or that duplicate and overlap other well documented research; the elimination of the use of laboratory animals to produce research results of dubious value and application to the study of human response to radiation of all sorts; and the promotion of research alternatives and the advancement of modern, sophisticated research methods through the use of substantial incentive awards to the research community.

Respectfully submitted,

ELEANOR SEILING, *President.*

APPENDIX TO COMMENTS OF UNITED ACTION FOR ANIMALS, INC.

EXAMPLES OF MODERN RESEARCH METHODS WHICH DO NOT REQUIRE THE USE OF LIVE ANIMALS

1. Gamma-Irradiated Heart Cells in Vitro
2. In Vitro Interactions (Synergism) of Chemical Carcinogenis and Radiation.
3. Radiation Damage and Repair.
4. Radiation Research with Nuclear "Phantoms".
5. Radiation Inhalation.
6. Biological Effects of Radioactive Material on Cultured Cells.

Gamma-irradiated heart cells in vitro.—Scientists at Harvard University used rat heart cells in vitro (outside the body) to study the effects of acute doses of gamma radiation in post-mitotic (after dividing) mamalian cell function. Hearts from 28 new-born rats were excised and kept alive and beating in suitable nutrient solutions. Seven days after "seeding" the culture cells, the scientists irradiated them at doses ranging from 1,000 to 100,000 rads with a cobalt–60 (Co) irradiator. Following irradiation, the heart cells were incubated at 98.6 F for the 30-day period of the experiment. The beating rate of the heart cells in each of the cultures was measured daily with a "heated state" inverted light microscope. Two or three days after irradiation, beating in those cultures receiving 50,000 or 100,000 rads became arrhythmic (i.e., stopped beating for a few seconds, then beat quickly for the next few). Doses of 50,000 and 100,000 rads completed inhibited the culture from beating within 8 to 23 days, "indicating the functional limit of radiation these cells can tolerate." Doses of 10,000 rad or less did not affect the beating rate or rhythmicity, "although the overall cell density appeared sparser than in control cultures." Conclusions: The beating of heart cells in vitro allowed the physiological expression of radiation damage to be numerically measured. Loss of rhythmicity after gamma-radiation occurred much earlier than the loss of the ability of the cells to contract spontaneously. An advantage of the in vitro method of irradiating cultured heart cells is that it "eliminates the effects of vascular (blood vessel) damage," so that direct radiation injury to the cells themselves can be studied. The scientists said, "Maintenance of these cells for periods longer than 30 days may aid in identifying functional effects after irradiation with lower doses." (Int. J. Radiat. Biol., 28(1) : 99–102, 1975)

---

[4] A Toxicity Prediction System, developed by Genesee Computer Center, Inc., Rochester, N.Y. and Franklin Inst. Research Labs. Philadelphia, Pa., under partial sponsorship of the EPA, April 1977. Other techniques directly applicable to research in the radiation field are discussed in the appendix.

In vitro interactions (Synergism) of chemical carcinogenis and radiation.—Cancer toxicologists usually study the interaction of cancer-causing chemicals and radiation by dosing live animals with the chemicals and then irradiating them or vice versa. In contrast, a scientist at the National Cancer Institute used hamster cells to study this phenomenon. In addition to being "reproducible" and numerically measurable, the in vitro procedure for transforming normal mammalian cells into cancer cells "made possible the separation of events related to the process leading to transformation from secondary events that interfere with the early recognition of transformation." Exposure of the hamster cell strains to cancer-causing chemicals resulted in a dose-response relation which could be described mathematically by a "poisson distribution indicating that the transformation . . . is inductive [directly produced by the chemicals]." Pretreatment of the cells with ionizing radiation or "alkylating" chemicals (chemotherapeutic cancer drugs which in high doses are toxic to normal tissue) enhanced the frequency of transformation on a cell or colony basis "ordinarily obtained with known chemical carcinogens." Pretreatment with non-ionizing ultraviolet radiation did not have a similar effect. The two types of radiation and the alkylating agents reduced the efficiency of the cells to clone.

Radiation damage and repair.—Scientists at the University of Texas in Dallas used hamster lung cells in culture to study repair of radiation damage. Appropriate numbers of cells were plated onto petri dishes to yield about 200 colonies "in control and experimental dishes." The cells were than irradiated with x-rays at a dose selected to cause "potentially lethal" damage (i.e., damage which may be repairable to a non-lethal level if suitable conditions are provided). Immediately after exposure to a single radiation dose, cells were overlaid with either "FS–15" (complete growth medium) or "Earle's balanced salt solution." After a period of time in the balanced salt solution, buffer (the chemical balancing the solution) was discarded and cells were provided with FS–15 for colony formation. After 10 to 12 days of growth, cell colonies were counted. "Survival rapidly increased to a maximum after 1 hour in the balanced salt solution." This initial survival was followed by a decrease and then a second rise. "The initial increase observed . . . suggests that in the presence of buffer, mammalian cells repair potentially lethal damage." The subsequent fall in survival suggested that, during the repair process, an unstable cellular state occurred which prevented cell division in complete growth medium. Conclusion: A cellular environment which inhibits cell division is necessary if cells are to repair themselves following "potentially lethal" radiation damage. Further experiments on the cultured cells showed that their capacity for repair was also dependent on cell age. (Science, Vol. 165, Aug. 1, 1969)

Radiation Research with Nuclear "Phantoms".—Alderson Research Laboratories developed a life-like radiological test subject called "REMAB" (Railroad Equivalent Manikin-Absorption). These dummies or "phantoms" are equivalent to an average man in size and contours; they are filled with "a solution that has the same radiation-interaction properties as human soft tissues." REMAB was designed for radiation research and can be used for "depth-dose" measurements and "nuclear-accident re-creation." The dummies can be loaded with radioactive materials to determine the exposure effects to adjacent areas. ("Alderson Nuclear Phantoms," Alderson Research Laboratories, Inc., Stamford, Conn.)

Radiation Inhalation.—Over the past 30 years at institutions all across the country, animals have been forced to inhale radioactive materials. In contrast, scientists at Pacific Northwest Laboratories, under contract to the U.S. Atomic Energy Commission, designed a computer program that "permits rapid and consistent estimates of the effective radiation dose to the human respiratory tract and other organs resulting from the inhalation of radioactive aerosols." They also constructed mathematical models to describe the atomospheric dispersion of radioactive material "for the purpose of evaluating doses resulting from either accidental or chronic atmospheric releases of radionuclides." In the model, the respiratory tract was divided into three regions: the nasopharyngeal (nose-pharynx); the tracheobronchial (air passages to lungs; and the pulmonary (lung). The scientists employed "complex mathematics" to design the computer program input which consisted of several variables: duration of inhalation exposure, ventilation rate, time interval within which the dose is delivered, organs of interest, quantity of radionuclide inhaled, and "solubility class" and particle size. Output from the "CDC CYBER 74" computer consisted of the effective radiation dose to "any of 18 organs and tissues" in the human body. The model was extended "to include calculating organ doses resulting from chronic inhalation," as well as acute inhalation of radioactive particles. The scientists said that most of the basic data required to complete the calculations are available at "data libraries." The data in the libraries are set up such that "additional data or changes to existing data may be made with little difficulty." (BNWL–B–389 UC41, Dec., 1974).

Biological Effects of Radioactive Material on Cultured Cells.—Researchers at Rutgers University Agricultural Experiment Station are using cultured mammalian cells to test the damaging effects of tritium and other radioactive materials. They are conducting a comparative study of the chemical effects of radiation and of high energy, heavy ions (electrically charged atoms) and gamma rays on the isolated cells. Methods will be used to 'accurately" relate deposition and absorption of radioactive energy to biological damage. Though the work is still in progress, the scientists have already found "significant chemical differences between the effects of tritium beta rays and gamma rays." More interpretation is needed, but results so far are "potentially important since the present basis for tritium maximum permissible concentration assumes little difference between these radiations." (SSIE, Notice of Research Project, No. GY–C0353–4, July 1977)

UNIVERSITY OF OREGON HEALTH SCIENCES CENTER,
Portland, Oreg., June 13, 1977.

HON. WARREN G. MAGNUSON,
Chairman, The Senate Commerce Committee,
Russell Old Senate Office Building,
Washington, D.C.

DEAR SENATOR MAGNUSON: Your hearings on the adequacy of United States safety standards for microwaves and radiowaves are timely indeed. In recent years evidence has steadily mounted concerning the likelihood of low power level microwave cumulative dose effect hazards. It has also become apparent that certain federal agencies and private contractors have vested interests in obstructing the public scrutiny and adequate research support for accurate determination of the risks of these apparent hazards. Most people do not realize that certain types of non-ionizing radiation (e.g. microwaves and radiowaves) can have similar effects to the readily recognized dangers of ionizing radiation (X rays and gamma rays), with the principal difference being the much lower incidence of tissue damage due to the much lower energy content of the non-ionizing radiation. However, the lifetime accumulation of non-ionizing radiation dose, the damage to the posterior capsule of the ocular lens, and the suspicion of increased cancer risk are all characteristics in which the effects of non-ionizing radiation resemble those of ionizing radiation. The continuing rapid increase in use of radiowaves for military and civilian communication and sensor systems as well as the growing popularity of microwave cooking in the home, means that it is imperative to develop accurate and adequate health risk estimates from sources which cannot be accused of vested interest in health hazard information suppression. This will require epidemiologic and experimental research of a whole array of circumstances over considerable periods of time because of the intricate influence of environmental variables and the latent ueriod s between exposures and potential chronic disease manifestations.

A volunteer member of our faculty, Mr. William Bise, has been instrumental in bringing to our attention the fact that foreign scientists have gathered a great deal of evidence suggesting the existence of significant hazard from low level microwave radiation. He is an experienced radio broadcaster and has formed a non-profit corporation (Pacific Northwest Center for the Study of Non-Ionizing Radiation) for the purpose of promotion and support of investigation of these hazards. He is writing to you under separate cover. We endorse your efforts to look into this matter and anticipate the eventual facilitation of of radiowave health hazard investigation as a result.

Sincerely,

WM. E. MORTON, M.D., DrPH, *Professor*

PACIFIC NORTHWEST CENTER FOR THE STUDY OF NON-IONIZING RADIATION,
Portland, Oreg., June 6, 1977.

Hon. WARREN G. MAGNUSON,
U.S. Senate, Russell Senate Office Building, Washington, D.C.

DEAR SENATOR MAGNUSON: Enclosed is material that I would like to submit in lieu of verbal testimony in the upcoming senate subcommittee hearings on microwaves. In a telephone conversation with Sharon Nelson on Wednesday June 1, 1977, I pointed out that my limited budget does not allow me to appear in person. The material describes a pilot study of central nervous system radiofrequency (RF) effects which I conducted on ten human volunteers at a power level on the order of 67 microvolts per meter intensity, previous to founding a non-profit research corporation. As you know, Public Law 90–602 set the so called safe level for human exposure to this energy at about 195 volts per meter. The pilot study findings suggest that brain waves (and possibly behavior) are affected at specific frequencies at substantially lower power levels of RF than people can be exposed to in their daily lives. Whereas further research is necessary to verify or deny the pilot study findings, it is my opinion that a meaningful risk factor already exists for the population at large. The technical paper entitled Radiofrequency Induced Interference Responses in the Human Nervous System has been submitted for consideration in the upcoming URSI International Symposium on Biological Effects of Electromagnetic Waves to be held at Airlie, Virginia on October 30–November 4, 1977. Also enclosed is a popular technical article that I authored which describes the pilot study which appeared (without references) in the January 1977 issue of Communications/Engineering Digest.

I have worked out an experimental design using the ambient RF as a signal source for a follow up study. The design conforms to all H.E.W. guidelines for protection of human subjects. If funds can be granted for this research, many questions concerning RF biological hazards can be answered.

Electronics engineers are dedicated to designing, building and maintaining better and ever more sophisticated products for radiating and detecting all kinds of electromagnetic waves. With the exception of careful respect for high voltages, currents and power, a good engineer will insist that low power microwaves or radiowaves cannot possibly affect human behavior and/or health. As an engineer who held that view for fourteen years, I can attest to this fact. Except for a rather dramatic incident in 1970 involving my wife, who was nearby while I was troubleshooting some gear with a low power microwave generator, I might not have done a pilot study of RF effects; and I might still have remained unconvinced that low level microwaves/radiowaves are hazardous at specific frequencies.

Since I became a clinical instructor in environmental medicine at the University of Oregon Health Sciences Center, it has become apparent to me that most physicians are unaware that low-level radiowave biological effects can mimic many symptoms of various defined diseases. I have found the entire subject of radiowave hazards very unpopular to science, business, industry and the military; perhaps because recognizing these hazards would cause so many necessary changes in these various areas.

An international radiowave conflict has been going on for some time and was intensified dramatically in July 1976 with the addition of the Soviet 10 Hz pulses which may produce serious biological effects on people regardless of the real intent of these intense pulses of radiant energy. It is not necessary for nations to declare war of this nature since it is silent and invisible to our normal senses.

Using the legal power limit of 10 milliwatt per square centimeter, a malicious person could easily build (or buy surplus) equipment that could physically and mentally damage people, over a period of time, without the victim ever knowing what was happening to him. The members of the executive, legislative and judicial branches of government may even be more vulnerable to this kind of personal harassment than the ordinary citizen.

It is conceivable that special interest groups have already resorted to tactics of this nature. I was called as a consultant in April of 1976 in a case in Seattle, Washington where the microwaves and lasers which my instruments detected possibly were the result of personal harassment. One motive could be the desire to buy property at bargain prices from people who are anxious to sell in order to leave the neighborhood because they no longer feel well in their home or business. Because I was working alone in Seattle, my findings remain inconclusive. Military radar scatter also seemed to be one of the sources of radiation in the two different areas which I checked.

To paraphrase an engineer formerly with the North American Air Defense Command, "You'd never really know the cause of death from this stuff . . . . you could hit someone, coagulate their blood and no one would ever know what happened."

I hope that there is something that your committee can elicit from the upcoming hearings to at least inform, if not protect, the people of the United States from electromagnetic hazards. The specialization of science unfortunately limits the scientists' ability to bridge the interdisciplinary gap necessary to realize the urgent need for a joint effort of investigation into low power level microwave hazards.

There is another serious matter which involved a breach of security in Seattle concerning the President's "Doomsday" airplane. If at any time you might wish to talk to me, please let me know.

Sincerely,

WILLIAM BISE.

Enclosures.

RADIOFREQUENCY INDUCED INTERFERENCE RESPONSES IN THE HUMAN NERVOUS SYSTEM

(By William Bise)

Summary: Interest in lowpower athermal RF effects on biological systems has grown in recent years among American researchers and the foreign literature on the subject is prolific. Against this background a pilot study was conducted on five men and five women volunteers. Participants in a group of eight experiments completed from July 1975 through June 1976 were, of necessity, highly preselected. They ranged in age from 18 to 48 years. Three had been occupationally exposed to RF energy; the other seven had not and all were in apparent

good health. The RF ranges covered from .1 to 960 Mhz CW and 8.5 to 9.6 Ghz pulse modulated. Power levels were varied from 10^{-16} wt/cm^2 to 10^{-13} wt/cm^2. Three variable frequency low power output test alignment generators served as signal sources. Subjects were seated and oriented so that they could not see the equipment or the operator. During data gathering they did not know to what frequencies the sources were tuned nor did they know when the signal source was off or on. A 1 meter free space impedance coupled antenna was placed parallel to and 1 meter from the upper torso and head during CW tests. The open wave guide output of the pulse modulated source was oriented 1 meter from and perpendicular to the sternum. Any changes in the EEG traces were photographed from a cathode ray tube display and/or note was taken of the frequency which produced them. Previous to irradiation, the normal EEG tracings of the subjects were noted or photographed. Experimental time for each volunteer was typically 50 minutes. Tests were done at different times of the day at various locations, both in and out of a Faraday room. Signal source accuracy and power output levels, at the subject to antenna distance, were measured with two spectrum analyzers.

The EEG instrumentation used gave sequential recording of a single trace from an electrode pair and was specially designed for use in RF fields. Artifacts were identified and controlled out of the tests. Pushbutton switchable selectivity allowed sampling from the three different cranial areas without changing electrode placement. Plastic covered skin surface type electrodes were used.

Subjects' EEG traces displayed desynchronized alpha waves of 15 to 25 percent higher than normal amplitude and slow waves appeared at certain radiofrequencies. Conversely, diminution and desynchronization of alpha wave amplitude on the order of 20 to 50 percent occurred at other radiofrequencies and 2 to 6 Hz slow waves appeared. These two anomalous patterns were found in both men and women volunteers. Mental attitudes appeared to change during the tests. CW frequencies at a power density of about 10–15 wt/cm.^{2} which produced EEG changes in males, were found between 130 and 780 Mhz. Female volunteers' EEG alterations occurred between 350 and 960 Mhz. Pulse modulation tests on two males, at a power density of about 10-12 wt/cm ^{2} showed EEG changes around 9.1 and 9.15 Ghz. Brain waves changed almost immediately upon tuning a generator to a frequency which produced them and then almost immediately reverted to their normal patterns when the generator frequency was altered or turned off. Various lead configurations and antenna orientations were tried during the CW tests and demonstrated that active sampling from the right frontal parietal to the right occipital, with antenna presented 1 meter from left hemisphere, yielded repeatable results. This suggests that the right hemisphere is the more responsive one to RF energy. Experiments performed near noon and midnight showed the most significant EEG pattern changes thus a circadian biorhythm dependence may be involved.

Notably, the CW RF energy of about 67 microvolts per meter which was seen to alter brain waves is characteristic of the average EEG voltage level which exists at the surface of the head. The EEG changes seen in most of the participants were produced by this RF energy level at frequencies between 130 and 960 Mhz. Since most researchers agree that the relaxation frequency of protein bound water must lie between 100 and 1,000 Mhz, it is possible that resonance absorptions occurred. The shape of the human head (spherical antenna bandwidth), the piezoelectric characteristic of bone and the possible up and down frequency shifts of radio energy entering and leaving protein bound water in near surface tissue are considerations in this phenomenon. Altered EEG patterns resulting from electrical stimuli should be expected to reflect corresponding behavior changes. It is known that both the thalamus and hypothalamus are especially sensitive in this respect. The 6 Hz waves which appeared in some subjects' EEG patterns are similar to those waves associated with annoyance seen in earlier EEG research. Brain wave changes were triggered in alert volunteers by external energies which they could not perceive. At very low RF field densities the body's neurointegrative systems evidently do not function normally or somehow may be prevented from normal functioning. RF induced stimulation of the midbrain structures may be a fundamental factor. The full impact on biological systems of long exposure to low intensity RF energy is not known, but the likelihood of cumulative dose effects means that small doses are important.

MEDICAL COLLEGE OF VIRGINIA,
VIRGINIA COMMONWEALTH UNIVERSITY,
Richmond, Va., July 25, 1977.

HON. WENDELL H. FORD,
HON. ADLAI E. STEVENSON,
Committee on Commerce, Science, and Transportation,
U.S. Senate,
Washington, D.C.

DEAR SENATORS FORD AND STEVENSON: I am writing to you in reference to the U.S. Senate Committee on Commerce, Science, and Transportation hearings concerning the current status of health protection problems from radiation exposure. I have been involved in research related to the biological effects of ionizing and nonionizing radiation for the past twenty years and much of my research has been directed toward the establishment of safe exposure levels for humans.

My particular interest is the biological effects of microwave radiation, a topic that as you know is now much in the public view and presents a number of controversial aspects. In spite of the fact that recent research in this area has revealed a number of physiological and psychological alterations in various species of experimental animals, research support for such studies has been rather drastically reduced in the past few months. I fully realize that biologic effects of microwave exposure are but one of the many problems related to radiation exposure, but it is of great concern to me personally as a scientist and as a citizen, that sustained research support does not appear to be forthcoming for the solution of problems such as this. I believe we need answers now for the questions that will inevitably arise in the near future due to the ever increasing levels of occupational and nonoccupational exposure to microwave and radiofreqency radiation. Such answers can only be obtained by sustained research efforts which are difficult, if not impossible, in the face of drastic fluctuations in research support in areas such as this.

My views are based upon the results of research being conducted in my laboratory as well as a rather extensive review I have recently completed of the literature in this area. The results of this review are detailed in the enclosed article entitled "Biological Effects of Microwave and Radiofrequency Radiation." In view of the extent of this review article I would like to summarize a few of what I feel are the most salient points regarding human exposure to microwave and radiofrequency radiation:

(*a*) a significant number of studies conducted during the past six years in this country and the Soviet-bloc nations have revealed various physiological and psychological alterations in living systems at levels in the region of 10 mW/cm^2, the human occupational exposure standard in effect in the United States,

(*b*) although microwave-induced heating appears to play a role in the induction of such effects, there are qualitative and quantitative differences in the radiation effects compared to nonradiation heating,

(*c*) the reported effects of exposure of normal, healthy animals to low-intensity (ca 10 mW/cm^2) fields by and large appear to be reversible in nature, but chronic exposure (i.e. periods of weeks or months) results in immunological alterations suggesting that exposure of animals compromised by coincident exposure to, for example, pathogenic organisms or drugs may result in significantly enhanced effects. Multiple-stress microwave interactions could present a wide spectrum of problems in human populations due to endemic viral and bacterial pathogens and to the prevalence of drug usage. Although studies to ascertain the significance of such interactions have been proposed, such investigations are currently suffering from a lack of funding.

((*d*) In spite of the evidence indicating that low-intensity microwave and modulated radiofrequency and low frequency electromagnetic fields alter biological systems, the presently available data is not sufficient to enable basic interaction mechanisms to be determined.

I believe that the biological effects of electromagnetic fields pose significant problems that must be solved if we are to preserve the quality of our environment. Research in this area is for the first time beginning to define the true nature of the problem and it is also providing the data needed for the future development of exposure guidelines that will prevent deleterious effects. I urge you, therefore, to consider the necessity of supporting efforts for the funding of sustained research in this area.

I thank you for your interest in this matter and will willingly provide any additional information at my disposal to aid in your deliberations.

Very truly yours,

STEPHEN F. CLEARY, Ph.D.,
Professor of Biophysics,
Medical College of Virginia.
